This report shall not be reproduced, except in full, without the written approval of Southwest Research Institute®.  
Results and discussion given in this report relate only to the test items described in this report.

## **FOREWORD**

This project was conducted by Southwest Research Institute®(SwRI®) for the Environmental Protection Agency (EPA) under Work Assignment No. 0-2 of Contract EP-C-05-018. The assignment was titled “EPA 2006 Sulfur in Diesel Fuel Round-Robin Test Plan and Data Analysis”. The project was based on SwRI Proposal No. 08.42495 and was identified within SwRI as Project 03.11382.02. The EPA Project Officer was Mr. Robert Johnson, and the EPA Work Assignment Manager was Mr. Chris Laroo. Dr. Lawrence Smith was the SwRI Administrative and Project Manager, and Dr. Robert L. Mason was the Principal Investigator. Ms. Janet P. Buckingham assisted in the data processing and data analysis activities.

## EXECUTIVE SUMMARY

The 2007 Highway Heavy-Duty Diesel Rule of the Environmental Protection Agency (EPA) requires that 80% of the highway diesel fuel sold after June 1, 2006 contain 15 ppm sulfur or less. This regulation allows for a 2 ppm downstream test tolerance at the point of sale. Recent evaluations of the reproducibility of sulfur measurement test methods on a lab-to-lab basis have cast doubt on the 2 ppm downstream test tolerances. This concern caused EPA to construct a Round-Robin program to make an accurate determination of reproducibility. This Work Assignment addressed the data collected in this study and its analysis. The assignment focused on two separate tasks.

Task 1 involved reviewing EPA's test plan and data processing plan, and determining which statistical methods were better in identifying outliers. Recommendations were given on alternate techniques for excluding outliers and a detailed summary was provided on the merits of each technique.

Task 2 involved processing the data obtained from the EPA 2005 Ultra-Low Sulfur Diesel Fuel (ULSD) Round-Robin test plan and statistically analyzing the resultant data. The test plan included collecting sulfur measurements on five fuel samples for each of two months with measurements made in triplicate. The data were collected using two separate calibration methods (In-House and NIST). Statistical analysis of the sulfur data included two outlier deletion methods (robust and gravimetric) and two analysis techniques for computing reproducibility and repeatability (ASTM and ANOVA). For data collected on four different test instruments (D 5453, D 7039, D 2622, and EDXRF) and their composite, calculations were made of the mean, standard deviation, repeatability ( $r$ ) and reproducibility ( $R$ ) for each of the fuel samples and each of the calibration, outlier and analysis methods. The  $R$ -results were compared to the ASTM Interlaboratory Crosscheck Program (ILCP)  $R$ -values determined in 2004 and 2005.

There were three unique aspects of this round-robin test program compared to the 2005 ASTM ILCP. The first is that all of the labs that participated in this program were required to qualify their measurement method with EPA per 40 CFR 80.584.<sup>1</sup> The second unique aspect of the program is that two different outlier deletion methods, robust and gravimetric, were used. Even if a lab qualified a measurement method for a subset of the analysis, EPA further screened the labs based on whether they continued to meet the qualification criteria as determined through their ability to accurately measure a blind gravimetric standard. This gravimetric screening process can be analogous to the use of a calibration check standard, a widespread industry practice in many aspects of analytical analysis and one that is recommended by ASTM in their Crosscheck (CC) program.<sup>2,3</sup> Using the gravimetric outlier deletion method, the results of a lab were deleted if, for whatever reason, the lab could not demonstrate it had attained a level of accuracy that was similar to what was required during the initial qualification. The third unique aspect of the program is that, for a subset of the testing, labs were required to recalibrate their instruments using NIST standard reference materials (SRMs) that had recently been made available for use in the measurement of sulfur in ULSD fuel. Use of NIST SRMs and NIST traceable calibration standards is a common industry practice in many parts of analytical analysis, in order to reduce laboratory bias.

Overall trends in reproducibility noted from examining the data are given below.

- The gravimetric outlier deletion method produced lower R-values than the robust outlier deletion method.
- The R-values using NIST SRMs for instrument calibration were lower than the R-values using In-House standards for instrument calibration.
- The R-values for D 5453 and D 7039 were superior to those for D 2622 and EDXRF, although the EDXRF values may have been affected by the small sample size.
- The ANOVA method more often produced similar or slightly lower R-values than the ASTM method for D 7039, D 2622, and EDXRF, regardless of the calibration, but the results were mixed for D 5453 with the ASTM method being superior when combined with the NIST calibration.

Based on regression fits to the R-data and predictions at 15 ppm sulfur, lower predicted R-values occurred with the EPA Round-Robin (RR) results relative to the 2004 and 2005 ASTM ILCP results. The EPA RR predicted values were lower for D 5453 and D 2622, and the predicted values were comparable for D 7039. The reproducibility data also supported the following conclusions:

- Of the labs that originally agreed to participate in the EPA RR program, 29% failed to qualify their measurement methods.
- Limiting the RR participation to labs that qualified their methods under 40 CFR 80.584 had a favorable impact on lowering reproducibility.
- Using the identical NIST calibration curve across the participating labs reduced curve bias contributions to reproducibility.
- A reduction in predicted R (at 15 ppm sulfur) for the EPA RR data over the predicted R-values obtained using the 2004 and 2005 CC data was apparent in all cases when using the NIST calibration curves. The magnitude of the reduction in predicted R (ASTM R, at 15 ppm) from In-House to NIST under robust deletion was 0.73 ppm on average for D 5453 and D 7039 (excluding D 2622).
- Several labs had problems calibrating their instruments using the NIST SRMs.
- Using the gravimetric outlier deletion method further improved reproducibility. Use of this method is analogous to periodic use of a calibration check standard. This is a common industry practice wherein, if a lab fails to properly measure the calibration check standard, testing is halted until the cause of the failure is corrected.
- Of the labs that initially qualified their measurement methods, 22% of the labs in July and 19% of the labs in August failed the gravimetric outlier determination check on their qualification.
- Some of the newer test methods produced results with lower R (D 5453 and especially D 7039).

## **1.0 INTRODUCTION**

The Environmental Protection Agency (EPA) issued Work Assignment No. 0-2 of Contract EP-C-05-018 to Southwest Research Institute (SwRI<sup>®</sup>) in March 2005. The objectives of the work assignment were as follows:

- Review and comment on EPA's test plan, proposed data processing, and proposed methods of calculating reproducibility for its 2005 Ultra-Low Sulfur Diesel (ULSD) Round-Robin (RR) test program;
- Receive and process the sulfur diesel data to be collected by the participating labs and create an electronic file of the results; and
- Perform statistical analyses on the submitted lab data, including calculating reproducibility values using the recommended procedures identified after the analysis review.

Details of the Work Assignment are provided in Appendices A.1 and A.2. Included in Appendix A.1 is a copy of the original Work Assignment. Included in Appendix A.2 are copies of Amendment No. 1, added to allow for the inclusion of more labs, additional calibrations, and expanded data analysis after the initial work assignment was approved; and Amendment No. 2, added to include more tables and plots in the Final Report.

## **2.0 DATA COLLECTION AND PROCESSING**

### **2.1 Test Design**

All laboratories participating in this round-robin program were required to qualify their sulfur measurement methods with EPA. This meant that the labs had to meet the precision and accuracy requirements given in 40 CFR 80.584 for each individual test method that it wanted to use on a lab-specific basis. The round-robin program was designed to accommodate ten fuel samples, five of which were sent to the labs participating in July 2005 and five of which were sent to the labs participating in August 2005. In addition, the labs were required to use two different calibration curves when measuring the sulfur concentration of the fuels.

### **2.2 Lab Selection and Participation**

At the start of the RR program, 161 labs and 207 instruments were registered with EPA. Some of these labs were unable to meet the qualification criteria with their existing instruments and, as a result, several purchased new equipment. A list of the number of instruments and labs that eventually qualified and participated in the program during the two-month study period, as well as a list of the number of those that dropped out of the program is given in Table 1. In July, 129 labs participated and they used 149 qualified instruments. In August, 125 labs participated and they used 143 qualified instruments. Some labs that participated in July were not able to participate in August due to disruptions caused by Hurricane Katrina. A complete list of the labs that participated in the study is given in Appendix A.3.

**Table 1. Instrument and Lab Count by Test Method and Study Month**

<b>Test Method</b>	<b>July 2005</b>	<b>August 2005</b>	<b>Dropped Out</b>
D 5453	98	93	27
D 2622	25	24	23
D 7039	16	16	3
EDXRF	6	6	1
D 3120*	3	3	3
D 7041**	1	1	0
D 4294	0	0	2
Total Instruments	149	143	59
Total Labs	129	125	32

\* Only used in the Composite calculations.

\*\* Not used in any of the analyses.

### **2.3 Test Methods**

The participating labs qualified their instruments on one or more test methods, including D 5453, D 2622, D 7039, EDXRF, D 3120, and D 7041 (i.e., see Table 1). Since at least six different labs needed to participate for a specific test method in order to meet the criteria for a round-robin study, the counts on D 3120 and D 7041 were too small to qualify them as separate

test methods. In addition, since only one lab used D 7041, its data was excluded from all analyses. However, the data from D 3120 was sufficient to include it in the composite results. Thus, statistical analyses data were available from four separate test methods (D 5453, D 2622, D 7039 and EDXRF) as well as from the composite consisting of the data from these four methods and method D 3120.

## 2.4 Fuel Types

EPA targeted blending 10 diesel fuels in the 7-15 ppm sulfur range though the estimated sulfur concentrations were in the 7-21 ppm range. The fuels were blended on a mass basis from three different diesel fuels: a nominal 0 ppm S fuel, a nominal 9 ppm S fuel, and a nominal 350 ppm S fuel. Each sample was blended and bottled in a single batch, and the sample was constantly stirred during the process.

A list of the target fuel samples and the corresponding estimated concentrations based on the measured lab composite means are given in Table 2. Five blind fuel samples were sent to the labs in the months of July and August. The samples were not submitted for independent analysis to measure the actual sulfur concentration. One blend, Sample No. 5, was sent out both months to allow for a direct month-to-month comparison of the lab results. A natural-matrix gravimetric fuel sample, whose sulfur content was determined by Isotope Dilution Thermal Ionization Mass Spectrometry, was also sent out each month; it was labeled as Sample No. 4. The other eight fuel samples varied in sulfur content according to the range given in Table 2.

The gravimetric fuel sample consisted of the NIST Standard Reference Material (SRM) 1616b that measured 8.41 +/-0.12 ppm sulfur in kerosene. The sample was dyed yellow (it was initially clear) with Oil Yellow B to disguise it, allowing it to look similar to the other fuel samples. Oil Yellow B was analyzed for sulfur and was found to contain 67 mg/kg (thus the sulfur was more of a contaminant in the dye rather than a main component). A total of 80.3 mg of dye was added to 12 liters of SRM 1616b to dye the sample. Based on this, it was calculated that the sulfur contribution of the dye to the sulfur content of the dyed SRM 1616b was 0.000517 ppm, or essentially zero.

The gravimetric fuel sample was to be used in implementing the gravimetric outlier deletion method, a surrogate to a calibration check standard. The sample was a refined ultra-low-sulfur-in-kerosene standard, and was one of the NIST SRMs provided to the labs for generation of the NIST SRM calibration curve. It was expected that, if the instrument was calibrated with the same blind gravimetric standard that was used as a check standard, the lab should be able to accurately measure it as a blind fuel sample within the range for which it had been required to qualify. Note that the gravimetric outlier deletion procedure used in this program is not a statistical determination of whether a lab is an outlier, but rather a test to determine if a lab is still performing at approximately the same level of accuracy that the lab stated when it qualified.

It is important to note that EPA's lab qualification procedure does not guarantee that all labs can measure a known gravimetric standard accurately. Variation in the calibration standards used during calibration can lead to variation in results across different labs. By moving to the use of NIST SRMs and NIST traceable calibration standards, lab bias due to inaccuracies in

current in-house calibration curves can be limited. This is a standard industry practice in many other aspects of analytical analysis.

**Table 2. Targeted and Estimated Sulfur Concentrations (ppm) for Fuel Samples by Month**

Fuel No.	July Blend Target	July Composite Mean*	August Blend Target	August Composite Mean*
1	7	7.31	9	10.05
2	11	10.71	13	14.42
3	16	20.86	17	17.8
4	8.41	8.32	8.41	8.32
5	15	14.69	15	14.76

\* Average of the two composite robust means taken from the In-House and NIST calibration data.

## 2.5 Calibration Methods

Labs were required to measure the blind fuel samples in triplicate using two different calibration methods. The first method consisted of using the lab's existing "In-House" calibration curve. The second method was based on generating a four-point calibration curve using four NIST SRMs provided by EPA. The SRMs used in the generation of the curve are as follows:

- RM 8771  $0.07 \pm 0.014$  ppm S in diesel fuel
- SRM 1616b  $8.41 \pm 0.12$  ppm S in kerosene
- SRM 2723a  $11.0 \pm 1.1$  ppm S in diesel fuel
- SRM 2770  $41.57 \pm 0.39$  ppm S in diesel fuel

NIST SRMs were used to determine the contribution of calibration-standard bias to reproducibility. Poor choice in calibration standards across labs can cause labs to report differing and incorrect sulfur values for the same sample. A recent review of the 2004 ASTM ILCP has reported that site precision contributed 52.9% to reproducibility variance for D 2622 and 54.6% for D 5453, while lab bias contributed 30.6% to reproducibility variance for D 2622 and 33.8% for D 5453. The reasons cited for lab-specific bias were as follows: the test method instrument calibration was not correct; the source of gravimetric standards was inconsistent; the check standard was outside the range of analysis; the check standard had aged; and the incorrect check standard with respect to matrix effects was used.<sup>4</sup> Based on this analysis, one large source of lab-specific bias can be attributed to the selection of the calibration standard.

In any testing regime where accuracy is important, standard industry recommendations are that labs use the most accurate calibration standards that are available to them. NIST SRMs provide a highly accurate means of generating a calibration curve. The sulfur levels in the natural matrix SRMs used in this program are determined using Isotope Dilution Thermal Ionization Mass Spectrometry.<sup>5</sup> This is an isotope-based mass analysis and is highly accurate. Quality control checks of instrument stability, precision, and bias are also part of the guidelines established in ASTM D 6299-02 "Standard Practice for Applying Statistical Quality Assurance

Techniques to Evaluate Analytical Measurement System Performance".<sup>6</sup> In the paper on "ASTM D02 Interlaboratory Cross-Check Program Aids-To-The Analyst", it is recommended that, when choosing calibration curve and QA/QC check standards, labs should purchase a set of NIST sulfur-in-diesel-fuel-oil SRMs. The document states that the standards should be used to assist in the development of calibration curves and for checking secondary standards.<sup>2</sup> Use of NIST calibration check standards is also recommend by the ASTM ILCP for use in their ULSD ILCP as of April 2004.<sup>3</sup>

## **2.6 Data Processing**

Individual labs submitted their data by e-mail directly to SwRI using an Excel data sheet provided by EPA. Labs were assigned unique identification code numbers to keep their true identities confidential. The entire list of the lab data, which includes 8,760 sulfur measurements and the corresponding deletions, is given in Appendix B.

### **3.0 OUTLIER AND REPEAT DELETIONS**

Figure 1 contains the data analysis flowchart used in this study for the data collected for each month, fuel sample, and calibration method. Notice that its first steps are to delete either outlier values or outlier labs. To accomplish this objective two methods of outlier deletion were used in this program: robust outlier deletion and gravimetric outlier deletion. The robust outlier deletion method is currently in use in the ASTM ILCP. It involves deleting an individual sulfur measurement, and it does not require known fuel sulfur values for any of the fuel samples.

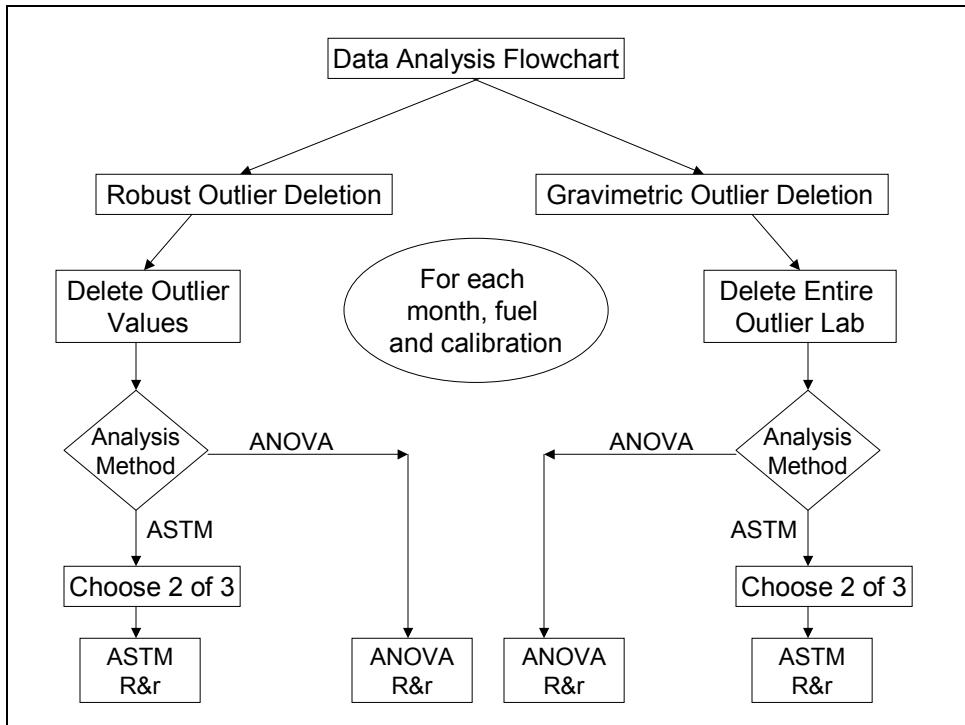

The gravimetric outlier deletion method is an alternative approach proposed by EPA. It involves deleting all the sulfur data collected by a lab for a given month if it failed a calibration check standards test intended to ensure that labs were still performing as required when they qualified their test method. It is a possible approach when known gravimetric fuel standards exist, as in this case. It can be seen as a surrogate to a calibration check standard. If the instrument, after being calibrated, can no longer measure one of the calibration standards accurately, then this indicates a problem with the instrument, the calibration curve, or the fuel samples (contamination). Subsequently data taken around the time that this check standard failure is noticed should be deleted and the instrument fault corrected before testing resumes (standard industry practice). The use of the calibration check standard should be periodic, but more frequent as the need for accuracy increases. If labs passed this test, all of their data was kept, regardless of whether individual test points may have been deemed outliers using the ASTM robust outlier deletion procedure.

#### **3.1 Robust Outlier Deletion Method**

The robust outlier deletion method is described in the Work Statements in Appendices A.1 and A.2. It requires computing the robust mean, RBM, and the robust standard deviation, RBSD, for each combination of fuel sample, test method and calibration curve using a procedure that limits the influence of unusually large or small values. As used in the ASTM ILCP, the calculation only uses two repeat measurements. For this round robin, samples were measured in triplicate; thus one of the three results was randomly deleted. Inclusion of the third repeat in the calculation might have further improved reproducibility. In this method, an individual lab repeat value, Y, is classified as an outlier and deleted from consideration if the following condition is met:

$$|Y - RBM| > 3 * RBSD.$$

Stated more simply, if Y is outside the limits of  $(RBM \pm 3 * RBSD)$ , then Y is classified as an outlier and deleted from the analysis. Note that the use of an error of  $\pm 3 * RBSD$  is standard ASTM practice. A number smaller than 3 would exclude more data and result in improved R.

**Figure 1. Data Analysis Flowchart**

### 3.2 Gravimetric Outlier Deletion Method

The gravimetric outlier deletion method is described in the Work Statements in Appendices A.1 and A.2. It involves computing the average, AVG, of the three repeat tests taken on the gravimetric standard fuel sample for a given month by a given lab. The gravimetric standard fuel sample in this program is either the July or August Fuel No. 4 (i.e., see Table 2 for a listing of the fuel samples). In this method, the data collected on all five fuel samples for a given month by a given lab are classified as outliers and the entire set of lab data is deleted if:

$$|AVG - ARV| > 0.90,$$

where the accepted reference value (ARV) of the gravimetric standard fuel is 8.41 ppm. Stated more simply, if AVG is outside the limits of  $8.41 \pm 0.90$ , which equate to the interval 7.51 to 9.31, all the lab data for the given month is deleted from the analysis. The 0.90 ppm limit for three repeat measurements was intended to be analogous to the 0.54 ppm limit for ten repeat measurements as outlined in the qualification accuracy requirements. The 0.90 ppm value takes into consideration the 0.54 ppm accuracy requirement, the 95% two-sided confidence limits (CL) for three repeat measurements, as well as real bias and gravimetric standard uncertainty (GSU). The calculation of the limit is given below:

$$\begin{aligned}
 \text{Limit} &= 0.54 - (95\% \text{ CL})^{10-1} + (95\% \text{ CL})^{3-1} + \text{GSU} \\
 &= (0.54 - 0.298 + 0.543 + 0.12) \\
 &= 0.905
 \end{aligned}$$

where the 95% CL calculations assume infinite degrees of freedom and use 0.48 as the standard deviation, and the GSU is 0.12. Infinite degrees of freedom are used because the exact number of labs that participated in the 2002 ASTM round robin with D 3120 and the number of results that went into the standard deviation determination was not known at the time this calculation was derived (in reality the number of labs was eight). The value 0.48 is the standard deviation given in D 3120 at 15 ppm, which is used in 40 CFR 80.584 in the determination of the precision and accuracy requirements.

### 3.3 Outlier Deletion Comparisons

Tables 3 and 4 contain an example comparison of the effects of the robust deletion method on the robust mean and robust standard deviations for the composite July fuel sample sulfur measurements for both the In-House and NIST calibration methods. Given in each table are the means or standard deviations for all the sulfur data in the specified data subset (i.e., all three repeat fuel measurements from each lab) as well as the robust means (std. devs.) computed both before and after the identified outliers have been deleted from the specified sulfur data subset. To compute the “robust mean before robust outlier deletion”, the ASTM ILCP calculations were used to estimate the robust mean during the first-stage before any outliers were deleted. After the ILCP identified the outliers (see Section 3.1), they were removed and the robust mean was recomputed during the second-stage of the ILCP calculations. This mean is labeled the “robust mean after robust outlier deletion” in Table 3. The last column of the table lists the total number of outliers deleted in the above process.

**Table 3. Sulfur Means for Composite July Data Using Robust Deletion Method**

Calib. Method	Fuel No.	Mean of All Data	Robust Mean Before Robust Outlier Deletion	Robust Mean After Robust Outlier Deletion	No. of Outlier Data Points Deleted
In-House	1	7.26	7.25	7.24	9
	2	10.66	10.66	10.65	8
	3	20.77	20.80	20.80	9
	4	8.29	8.26	8.25	7
	5	14.68	14.65	14.63	12
NIST	1	7.44	7.38	7.36	13
	2	10.89	10.83	10.80	18
	3	21.15	20.97	20.90	24
	4	8.50	8.42	8.38	31
	5	14.95	14.83	14.79	27

In Table 3, after deleting outliers and using a robust procedure to compute the fuel sample means, the resulting robust sulfur means are slightly smaller than the means based on all the data in all but one case for the five July fuels. This result holds regardless of the calibration

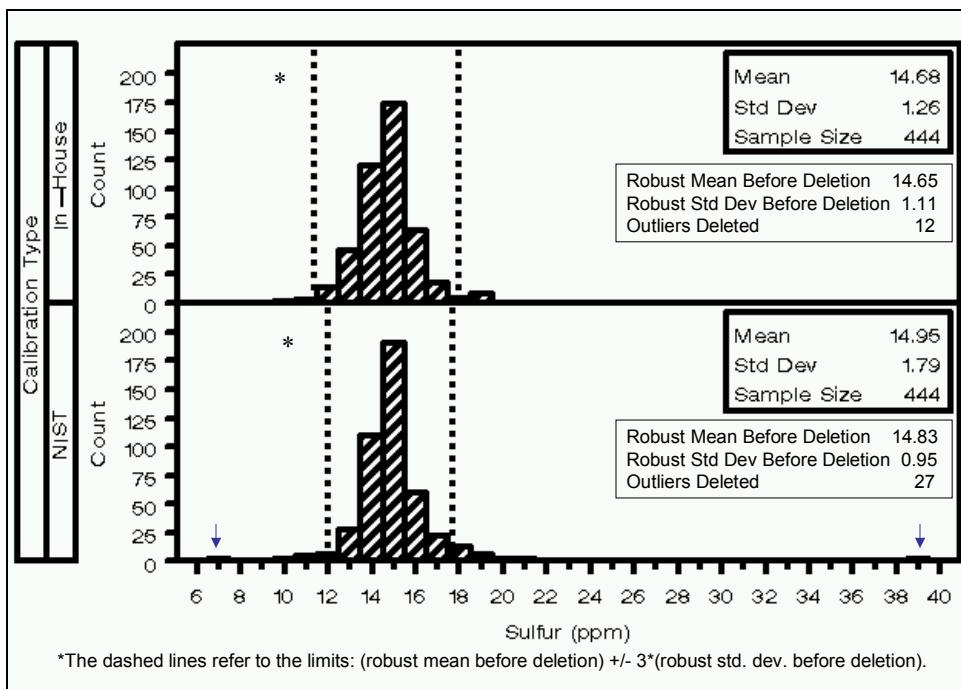

method. The exception is for the July In-House Fuel No. 3 where the robust mean had a slight increase.

In Table 4, after deleting the outliers and using a robust procedure to compute the fuel sample standard deviations, the resulting robust sulfur standard deviations are smaller than the standard deviations based on all the data, for all five July fuels and both calibration methods. Further, the NIST data has smaller robust standard deviations, both before and after outlier deletion, than the In-House data.

**Table 4. Sulfur Std. Deviations for Composite July Data Using Robust Deletion Method**

Calib. Method	Fuel No.	Std. Dev. of all Data	Robust Std. Dev. Before Robust Outlier Deletion	Robust Std. Dev. After Robust Outlier Deletion	No. of Outlier Data Points Deleted
In- House	1	0.87	0.73	0.71	9
	2	1.01	0.89	0.86	8
	3	1.64	1.41	1.36	9
	4	0.75	0.69	0.67	7
	5	1.26	1.11	1.05	12
NIST	1	0.98	0.72	0.66	13
	2	1.03	0.80	0.73	18
	3	1.68	1.05	0.95	24
	4	0.92	0.62	0.52	31
	5	1.79	0.95	0.83	27

Figure 2 contains a histogram of the composite data for the July Fuel No. 5 having a target of 15 ppm. Note that the standard deviation for the entire sulfur data subset is larger with the NIST than with the In-House calibration, but, after using a robust procedure to compute the standard deviation, the resulting robust standard deviation is smaller with the NIST than with the In-House calibration. This result creates narrower deletion limits for the NIST data versus the In-House data, and thus more outlier deletions occur with the NIST data. (i.e., 27 with NIST and 12 with In-House).

**Figure 2. Histograms for In-House and NIST Data for Composite July Fuel No. 5**

Tables 5 and 6 contain an example comparison of the effects of the gravimetric deletion method on the robust mean and robust standard deviations for the composite July fuel sample sulfur measurements for both the In-House and NIST calibration methods. Given in each table are the means (or std. devs.) for all the sulfur data in the specified data subset as well as the robust means (or std. devs.) computed both before and after the identified outliers have been deleted from the specified sulfur data subset. The last column of the table lists the number of outlier values as well as the number of labs deleted in this process.

**Table 5. Sulfur Means for Composite July Data Using Gravimetric Deletion Method**

<b>Calib. Method</b>	<b>Fuel No.</b>	<b>Mean of All Data</b>	<b>Robust Mean Before Gravimetric Outlier Deletion</b>	<b>Robust Mean After Gravimetric Outlier Deletion</b>	<b>No. of Outlier Data Points (Labs) Deleted</b>
<b>In- House</b>	1	7.26	7.25	7.29	96 (32)
	2	10.66	10.66	10.75	96 (32)
	3	20.77	20.80	20.91	96 (32)
	4	8.29	8.26	8.33	96 (32)
	5	14.68	14.65	14.75	96 (32)
<b>NIST</b>	1	7.44	7.38	7.30	81 (27)
	2	10.89	10.83	10.77	81 (27)
	3	21.15	20.97	20.89	81 (27)
	4	8.50	8.42	8.34	81 (27)
	5	14.95	14.83	14.78	81 (27)

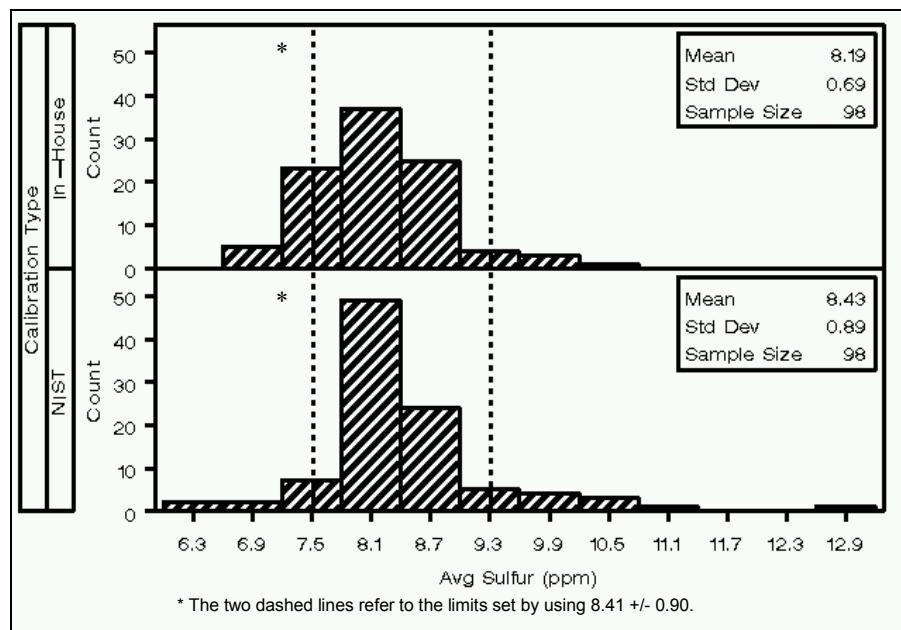

In Table 5, after deleting outlier laboratories gravimetrically and using a robust procedure to compute the fuel sample means, the resulting robust sulfur means are slightly larger than the means based on all the data for the five July fuels with the In-House calibration, and slightly smaller with the NIST calibration. The larger number of outliers when compared to the robust outlier determination for the NIST calibration curve is important in that it indicates that a large number of labs that had just calibrated using the four SRMs, including the SRM that is Fuel No. 4, could not measure Fuel No. 4 to within  $\pm 0.90$  ppm of the ARV. This is despite having previously qualified themselves to measure within this range.

In Table 6, after deleting the outliers and using a robust procedure to compute the fuel sample standard deviations, the robust sulfur standard deviations are smaller than the standard deviations based on all the data, for all five July fuels and both calibration methods. Further, the NIST data has smaller robust standard deviations than the In-House data.

**Table 6. Sulfur Std. Deviations for Composite July Data Using Gravimetric Deletion Method**

Calib. Method	Fuel No.	Std. Dev. of all Data	Robust Std. Dev. Before Gravimetric Outlier Deletion	Robust Std. Dev. After Gravimetric Outlier Deletion	No. of Outliers (Labs) Deleted
In-House	1	0.87	0.73	0.63	96 (32)
	2	1.01	0.89	0.72	96 (32)
	3	1.64	1.41	1.07	96 (32)
	4	0.75	0.69	0.48	96 (32)
	5	1.26	1.11	0.83	96 (32)
NIST	1	0.98	0.72	0.51	81 (27)
	2	1.03	0.80	0.62	81 (27)
	3	1.68	1.05	0.86	81 (27)
	4	0.92	0.62	0.42	81 (27)
	5	1.79	0.95	0.72	81 (27)

Figure 3 contains a histogram of the D 5453 data for July Fuel No. 4 with a target of 8.41 ppm. Note that the deletion limits are the same for both sets of calibration data. Since the mean of all the sulfur data is shifted to the left of the standard value of 8.41 for the In-House calibration and is nearly identical to 8.41 for the NIST original data, the number of outlier deletions is increased when using the In-House data. This result caused more outlier deletions for the In-House data in the plot despite its smaller standard deviation. The lower mean for the in-house curve versus the NIST curve can also be an indication of a downward bias in the in-house calibration curves.

**Figure 3. Histograms for In-House and NIST Data for D 5453 July Fuel No. 4**

### 3.4 Deletion of Extra Repeat Data

In preparing the data for the computation of reproducibility (R) and repeatability (r) using the ASTM Crosscheck method described in Section 4.0, it is first necessary to reduce the number of lab repeats from 3 to 2 when no outliers have been deleted. This is indicated in the data flowchart given in Figure 1. The method for doing this is described as follows. If all three repeats were determined to be valid data, the RANDBETWEEN function in Excel was used to randomly generate a data value (1, 2 or 3). If a “1” was randomly generated then the first repeat measurement was eliminated. If a “2” was generated then the second repeat was eliminated, and a “3” eliminated the third repeat.

Tables 7 and 8 contain a list of the number of outliers and the number of repeat values deleted when using either the robust deletion method or the gravimetric deletion method. The data are categorized by deletion method, test method, and calibration method.

**Table 7. Outlier and Repeat Deletion Counts for July Fuel No. 5 With Robust Deletion**

	Test Method	Total Count	In-House Calibration		NIST Calibration	
			Outliers Deleted	Repeats Deleted	Outliers Deleted	Repeats Deleted
<b>Robust Deletion</b>	<b>D 5453</b>	294	10	94	29	87
	<b>D 2622</b>	75	0	25	1	24
	<b>D 7039</b>	48	0	16	2	14
	<b>EDXRF</b>	18	0	6	0	6
	<b>Composite</b>	444	12	143	27	141

**Table 8. Outlier and Repeat Deletion Counts for July Fuel No. 5 With Gravimetric Deletion**

	Test Method	Total Count	In-House Calibration		NIST Calibration	
			Outliers Deleted	Repeats Deleted	Outliers Deleted	Repeats Deleted
<b>Robust Deletion</b>	<b>D 5453</b>	294	69	75	45	83
	<b>D 2622</b>	75	15	20	27	16
	<b>D 7039</b>	48	6	14	3	15
	<b>EDXRF</b>	18	0	6	3	5
	<b>Composite</b>	444	96	116	81	121

Using robust deletion, the results in Table 7 indicate that more outliers were removed with the NIST data than with the In-House data, though a similar number of repeat runs were deleted for the two calibration methods. This is a result of narrower limits and a smaller robust standard deviation after outlier deletion for the NIST data.

Using gravimetric deletion, the results in Table 8 indicate that more outliers were removed with the In-House data than with the NIST data, though a similar number of repeat runs were deleted for the two calibration methods. This is a result of the increased bias in the mean of the In-House data and the use of the same deletion limits for both sets of data.

Comparing the results of Table 8 with Table 7, it is seen that more values were deleted using the gravimetric deletion method versus using the robust deletion method. This is a result of the entire lab data for a given month being deleted if an outlier occurs in the gravimetric standard fuel values.

## **4.0 ANALYSIS METHODS**

Two different analysis methods were used in computing reproducibility ( $R$ ) and repeatability ( $r$ ): the ASTM Method and the ANOVA Method. Two major differences exist between these procedures. The first is that the ASTM method is applied to only two repeat sulfur values from a lab while the ANOVA method is applied to all three repeat values obtained by a lab on a given fuel sample. The second is that the ASTM procedure uses robust estimates of the mean and standard deviation in its computations while the ANOVA procedure uses unadjusted estimates of the mean and standard deviation.

As shown in Figure 1, both analysis methods were applied to the data using robust and gravimetric outlier techniques. Additionally, both the ASTM and ANOVA methods were applied to the In-House and NIST calibrations data.

### **4.1 ASTM Method**

This method requires further data deletion (after outlier deletion) to reduce the lab repeat count from 3 to 2 per fuel sample, when it occurs, as shown in the “Repeats Deleted” column in Tables 7 and 8. This was done in a random selection process for each test method analysis. The ASTM method uses the ILCP two-stage robust iterative algorithm to compute a robust mean and robust standard deviation with the remaining data. It then computes  $R$  and  $r$  using the above robust estimates.

### **4.2 ANOVA Method**

This method uses all available data after outlier deletion. It applies a one-factor random effects analysis of variance (ANOVA) technique and uses lab as the single factor. It estimates  $R$  and  $r$  using variance component estimates of lab (reproducibility) and of error (repeatability).

## **5.0 ANALYSIS RESULTS**

A variety of tables and plots were utilized in analyzing the sulfur data along with the analysis methods described in Section 4.0. Although several of these results are presented in this section, more can be found in Appendices C-F.

### **5.1 Descriptive Statistics**

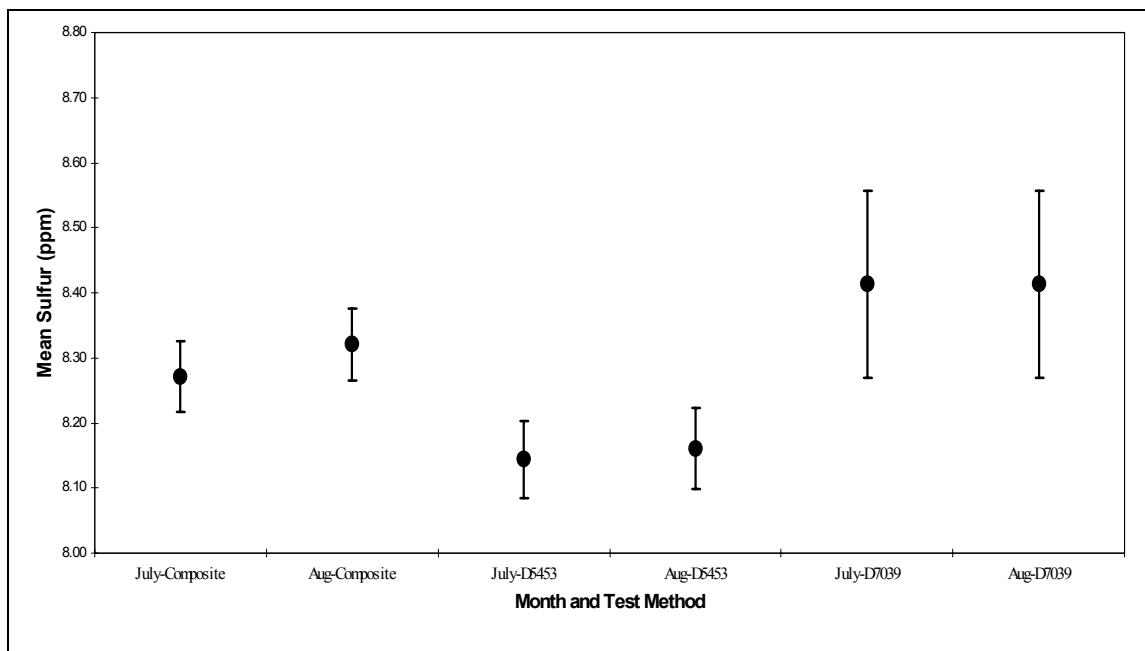

Appendix C contains a series of summary statistics (mean, standard deviation, and sample size) for the sulfur data. These are categorized by test method, calibration type, month, and fuel sample within month. Three tables are provided. Table C.1 contains the descriptive statistics for the data from all labs prior to any deletions. Table C.2 provides descriptive statistics for the data from all labs after deleting the outliers identified using the robust deletion method. Table C.3 provides similar statistics for the data from all labs after deleting the outliers identified using the gravimetric deletion method.

### **5.2 Mean Comparisons**

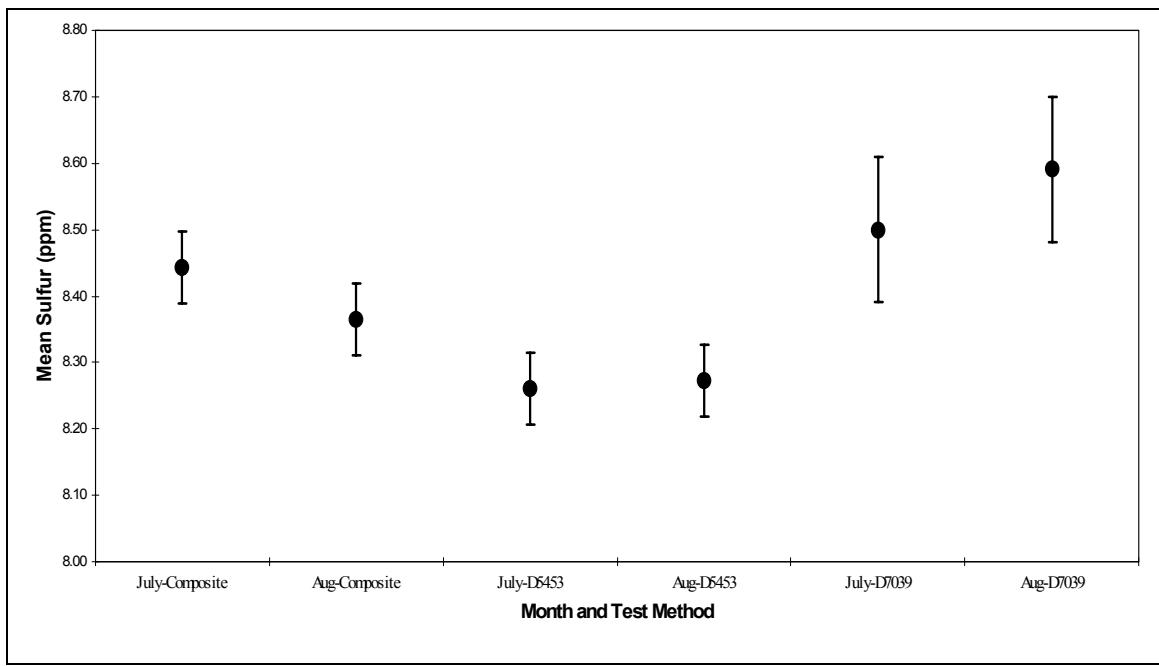

As reported in Section 2.0, test Fuels No. 4 and No. 5 were sent to every lab for both July and August. Therefore, it was possible to determine if the labs reported, on the average, similar results across the two months. Figures 4-7 provide plots of the July and August sulfur means for the Fuels No. 4 and No. 5 and the same test method. The data plotted are after the deletion of outliers using the robust deletion method, and after deleting the extra repeat values. Also included are 95% Tukey intervals around each mean. These intervals are constructed in such a way that if the two means are the same, the two intervals will overlap 95% of the time. Thus, if the two intervals for the July and August means being compared overlap, they indicate no significant difference between the two means being compared. If the two intervals do not overlap, the means are significantly different (at the 5% level of significance).

The means for the July Fuel No. 4 and August Fuel No. 4 samples are plotted together in Figures 4 and 5 using the composite, D 5453, and D 7039 test methods. These two fuel samples were chosen because they represent the gravimetric standard fuel having a sulfur target value of 8.41 ppm. Figure 4 contains the means for the In-House calibration and Figure 5 contains the means for the NIST calibration.

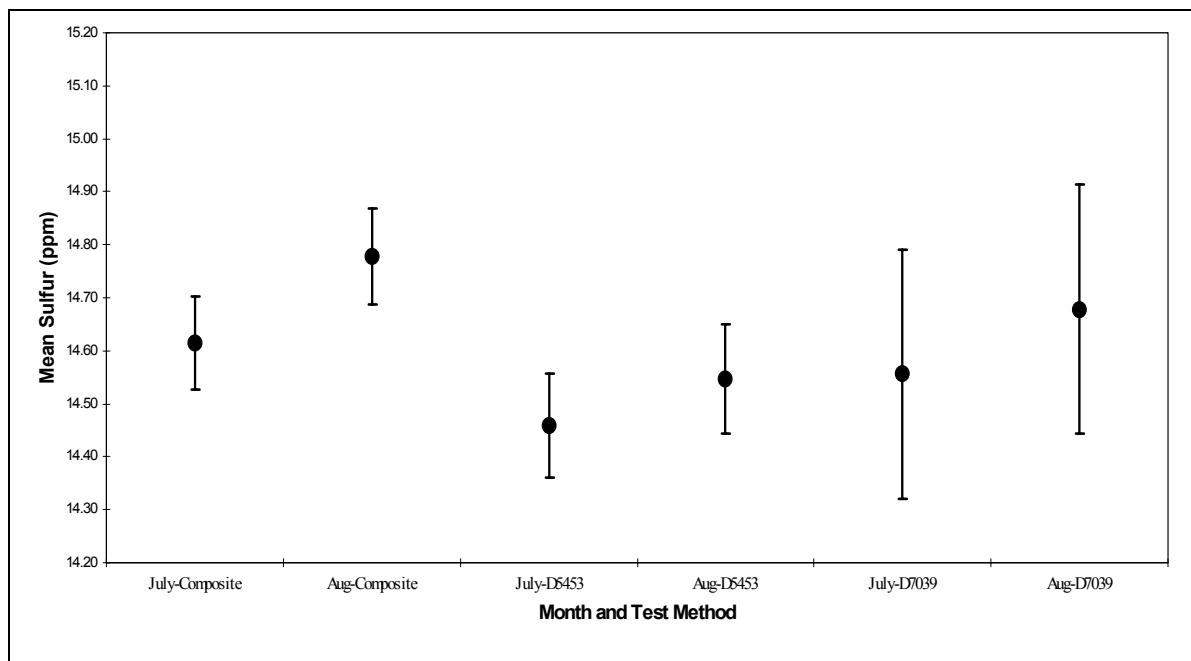

Similarly, the means for the July Fuel No. 5 and August Fuel No. 5 samples are plotted together in Figures 6 and 7. These two fuel samples were chosen because both have a sulfur target value of 15 ppm, which is the fuel sulfur level at which most of the reproducibility interest is aimed. Figure 6 contains the means for the In-House calibration and Figure 7 contains the means for the NIST calibration.

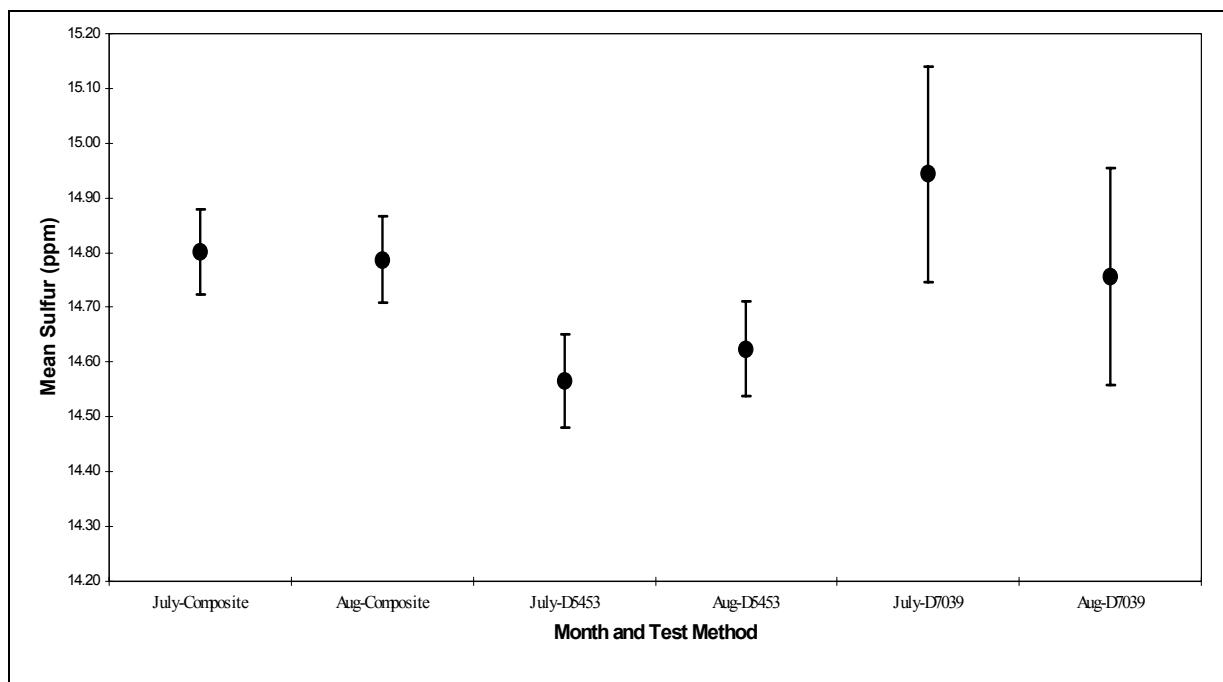

**Figure 4. Means and 95% Tukey Intervals for July and August Fuel No. 4 Data With Robust Outlier Deletion and In-House Calibration**

**Figure 5. Means and 95% Tukey Intervals for July and August Fuel No. 4 Data With Robust Outlier Deletion and NIST Calibration**

**Figure 6. Means and 95% Tukey Intervals for July and August Fuel No. 5 Data With Robust Outlier Deletion and In-House Calibration**

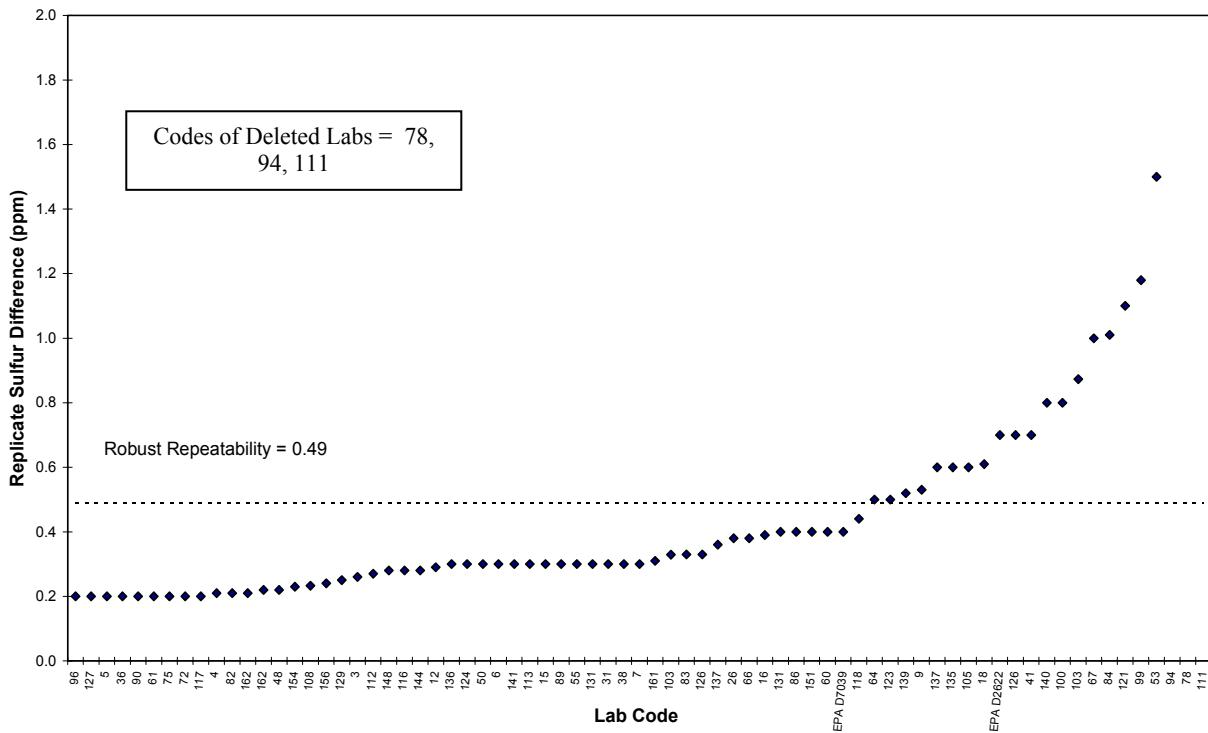

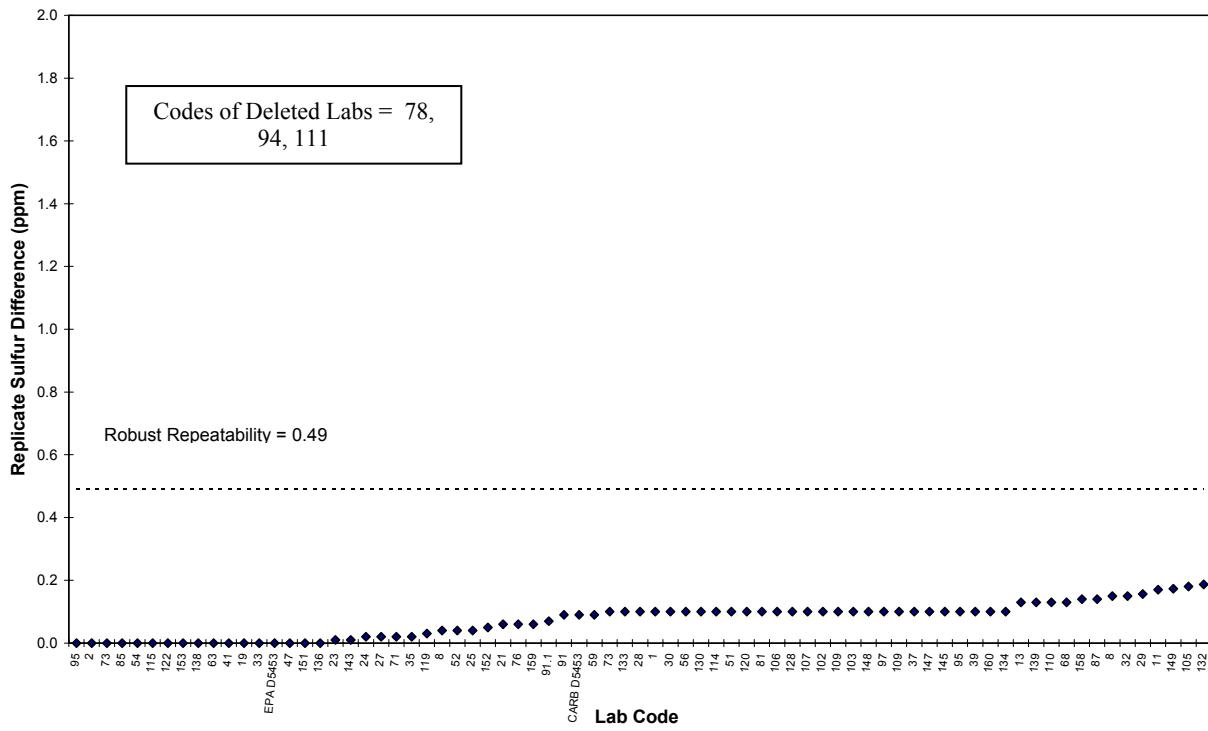

**Figure 7. Means and 95% Tukey Intervals for July and August Fuel No. 5 Data With Robust Outlier Deletion and NIST Calibration**

The means of the data, after all deletions (robust deletion and extra repeat deletion), for the July Fuel No. 4 and the August Fuel No. 4 were not significantly different using a 95% confidence interval with either calibration method. The same result holds for the mean comparisons for the July Fuel No. 5 and August Fuel No. 5 data. This was demonstrated separately for the composite, and for the D 5453 and D 7039 test methods. The results provide evidence that the sulfur means for the July and August samples of the same fuel did not differ significantly.

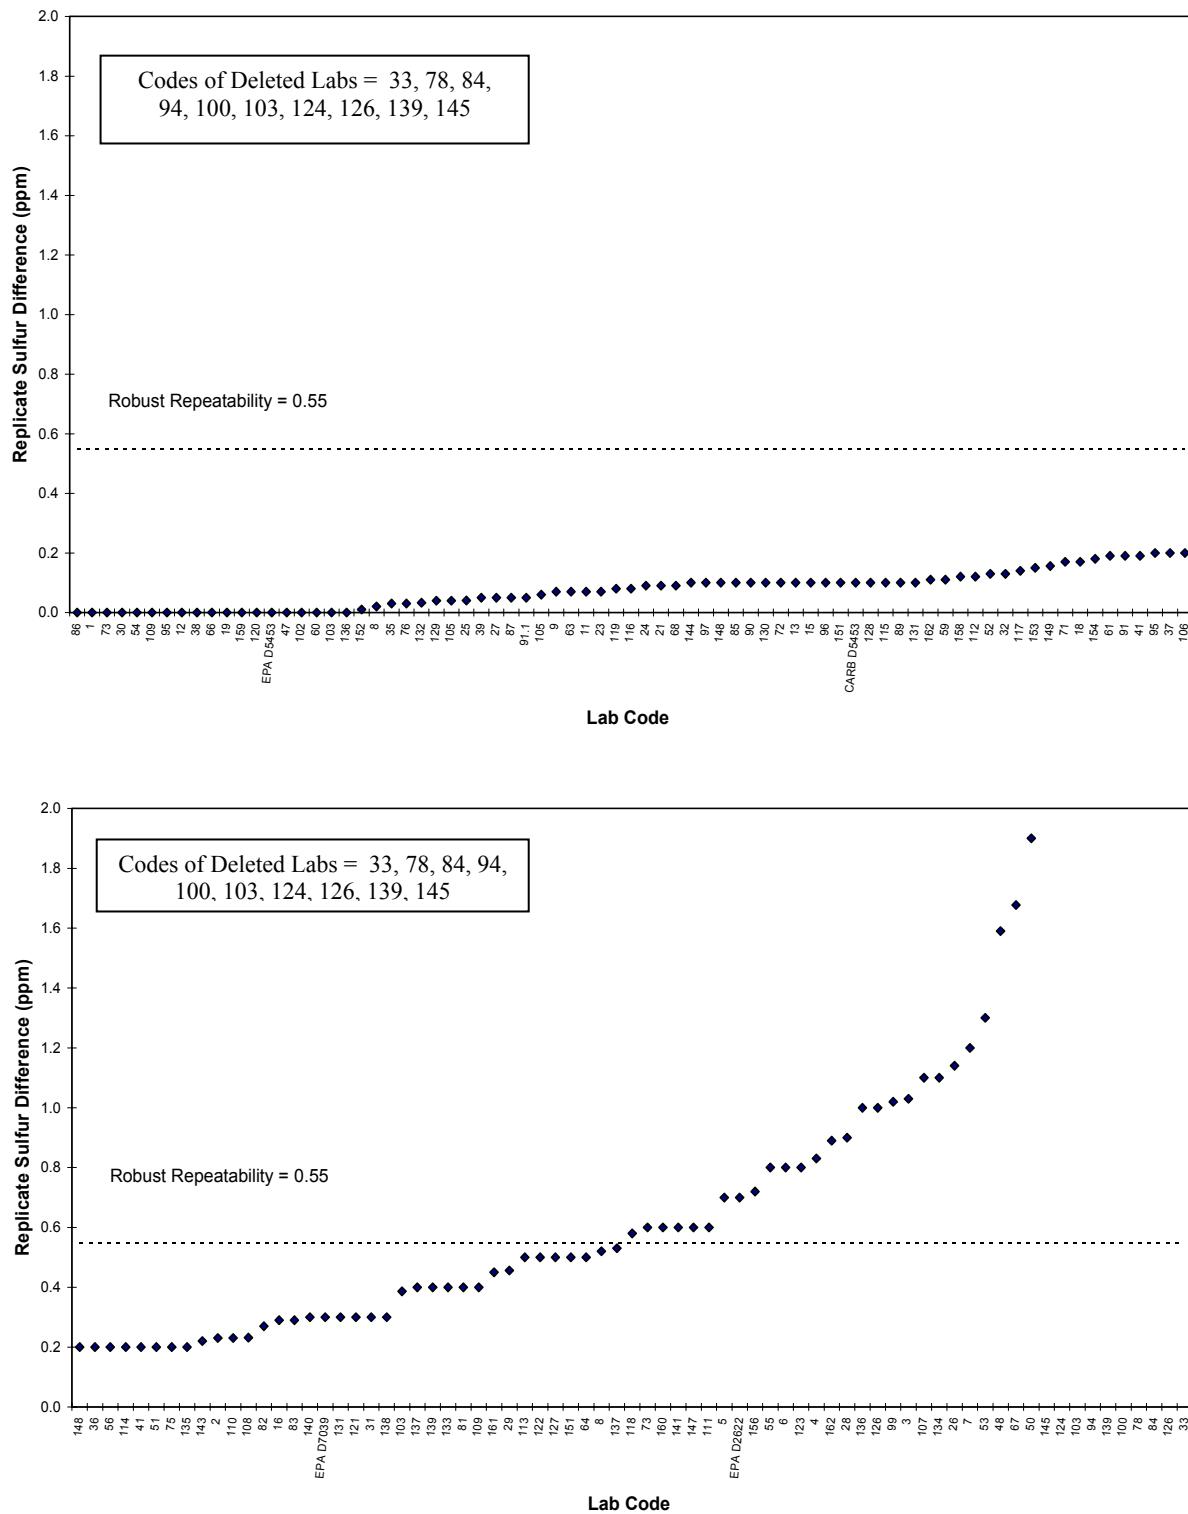

### **5.3 Comparisons of Lab ASTM Repeatability**

Figures 8-11 contain plots of the composite ASTM lab repeatability values computed with the robust outlier deletion technique and ASTM analysis. July Fuel No. 4 and August Fuel No. 5 data are represented for both the in-house and NIST calibration methods.

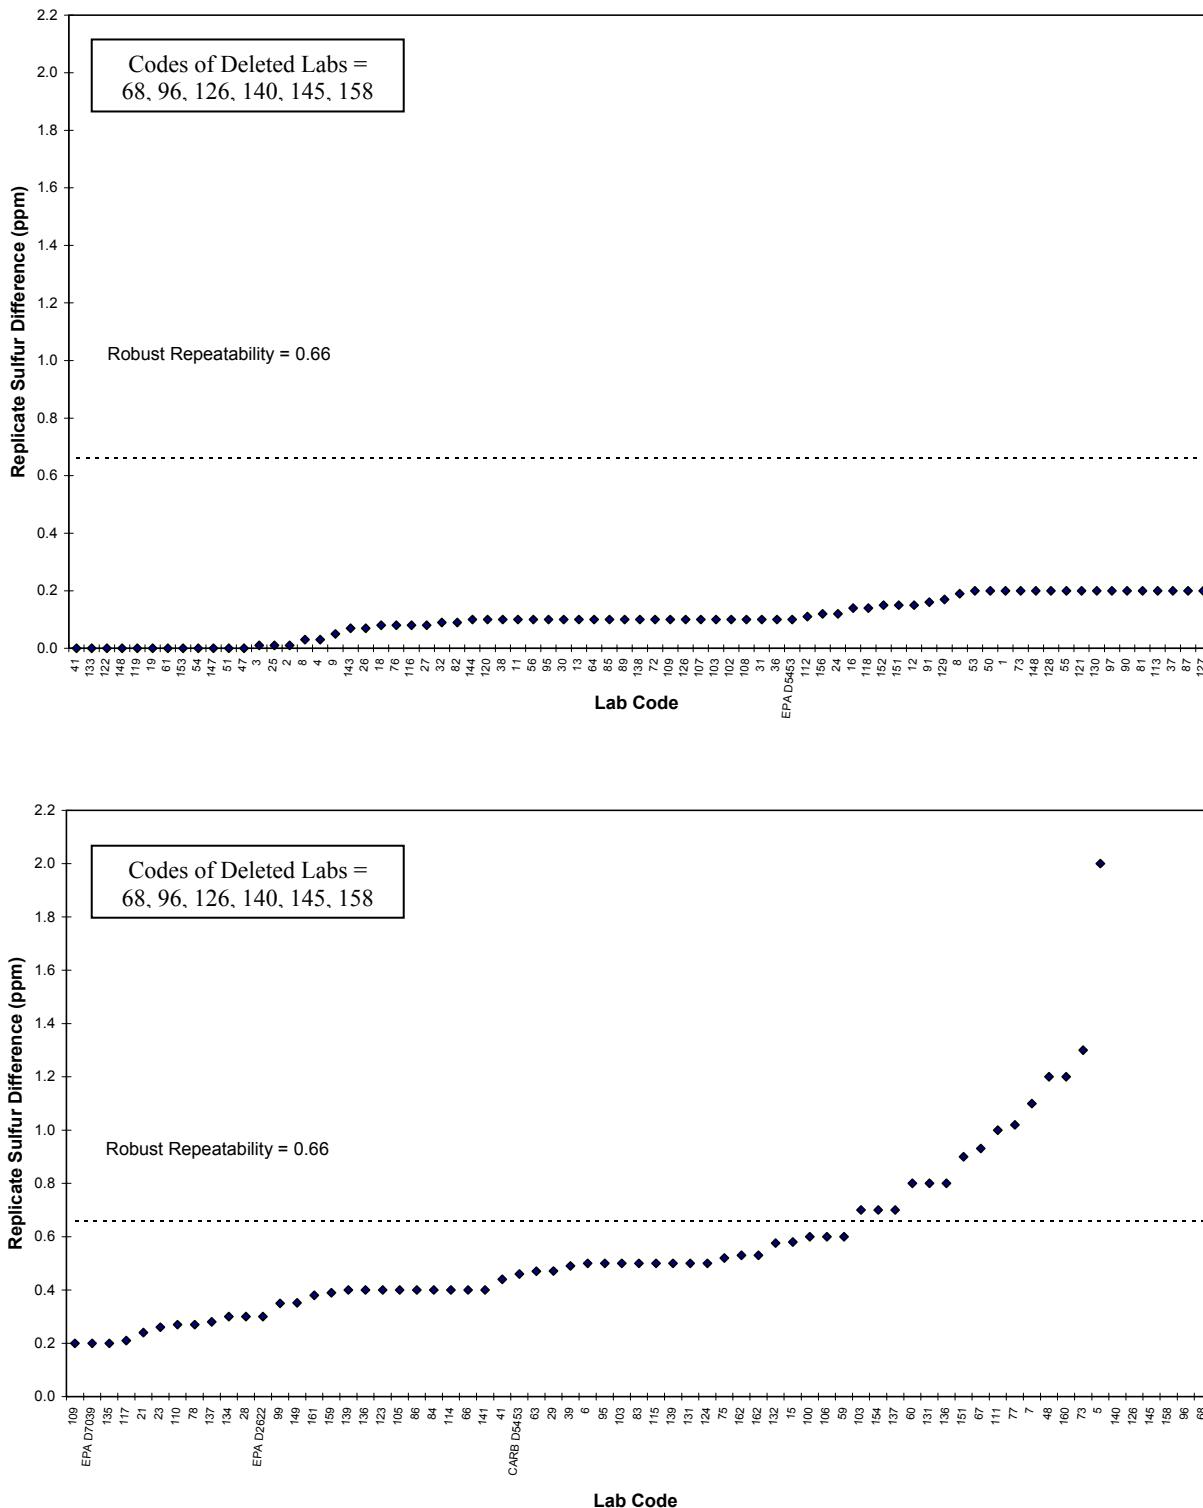

The differences between the two repeats are plotted against the lab code numbers, and the repeatability value for the composite data is included on each plot. This allows one to compare each lab repeat difference to the composite lab repeatability value. Differences that exceed the computed robust repeatability are readily identified. In addition, the code numbers of the labs that were deleted in the outlier and repeat deletion checks are listed in the figure. Note also that the code numbers for the EPA and CARB (California Air Resources Board) labs have been replaced with their abbreviated titles, namely EPA (used three independent instruments) and CARB, along with the corresponding test method number. Also note that some lab codes may occur multiple times, if they qualified multiple instruments.

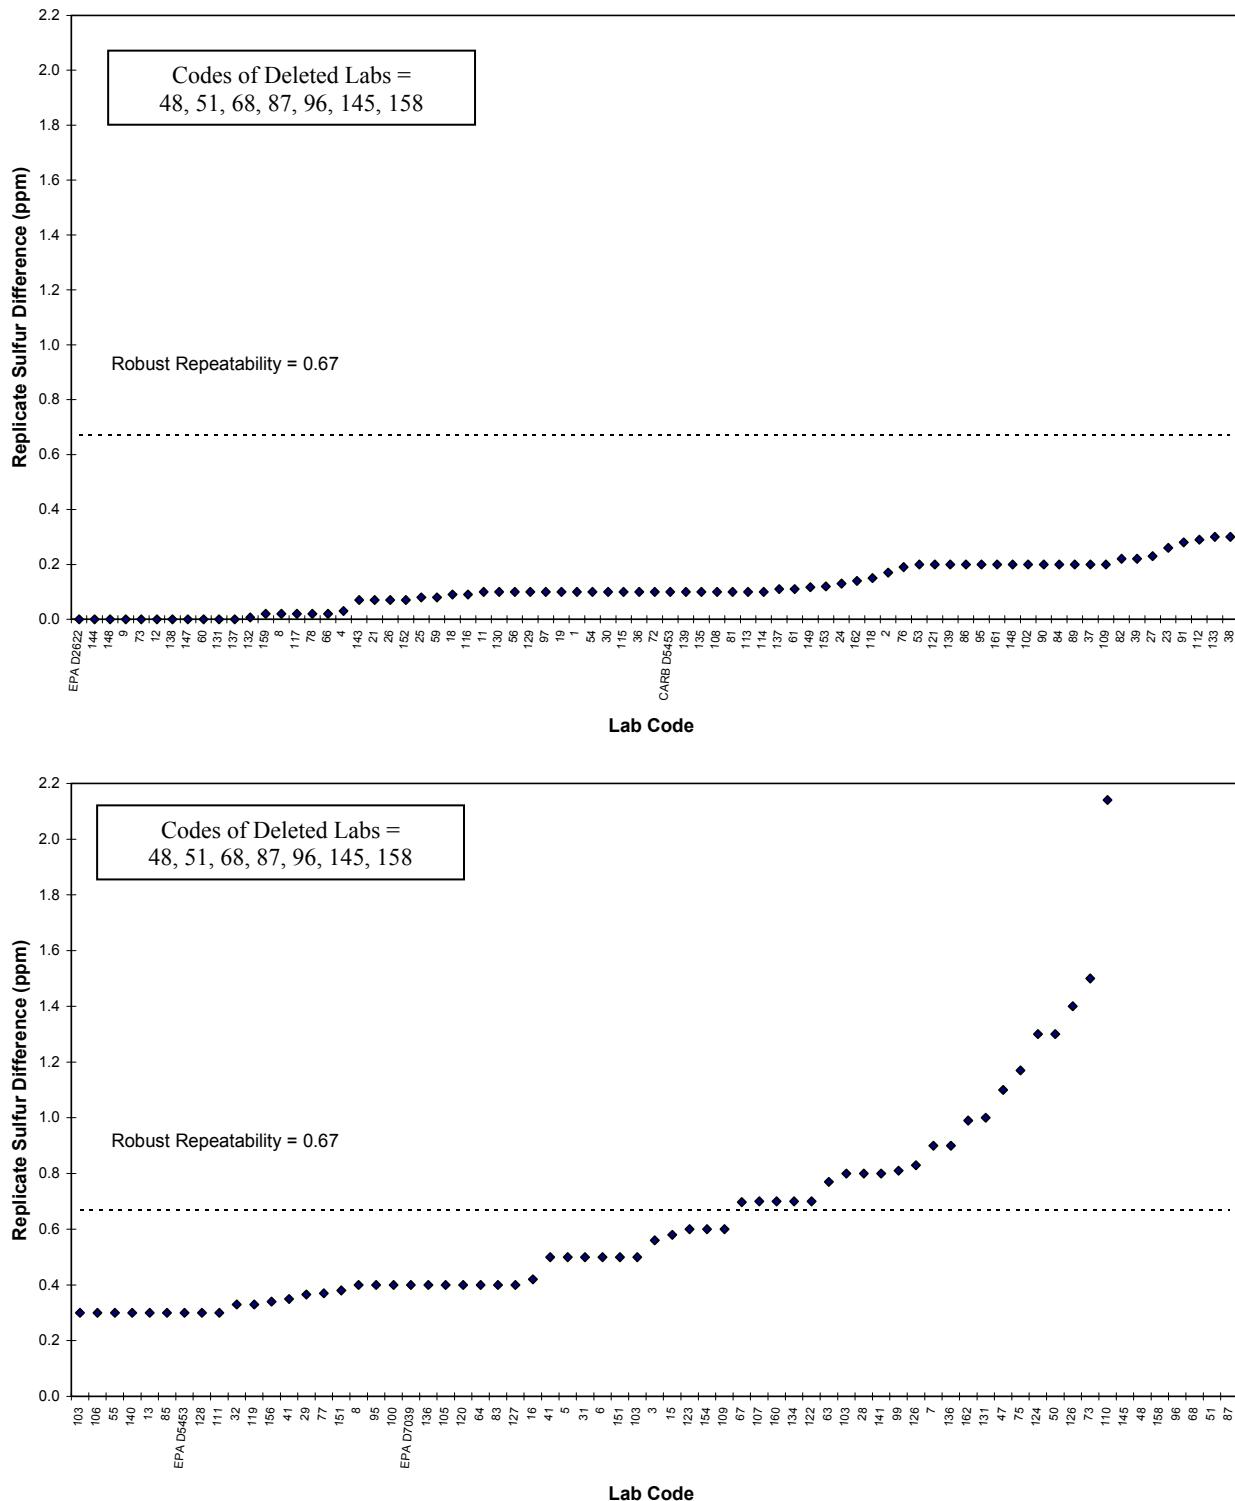

**Figure 8. Plot of Lab Replicate Difference vs. Lab Code for Composite Data for July Fuel No. 4 With Robust Outlier Deletion, In-House Calibration, and ASTM Analysis**

**Figure 9. Plot of Lab Replicate Difference vs. Lab Code for Composite Data for July Fuel No. 4 With Robust Outlier Deletion, NIST Calibration, and ASTM Analysis**

**Figure 10. Plot of Lab Replicate Difference vs. Lab Code for Composite Data for August Fuel No. 5 With Robust Outlier Deletion, In-House Calibration, and ASTM Analysis**

**Figure 11. Plot of Lab Replicate Difference vs. Lab Code for Composite Data for August Fuel No. 5 With Robust Outlier Deletion, NIST Calibration, and ASTM Analysis**

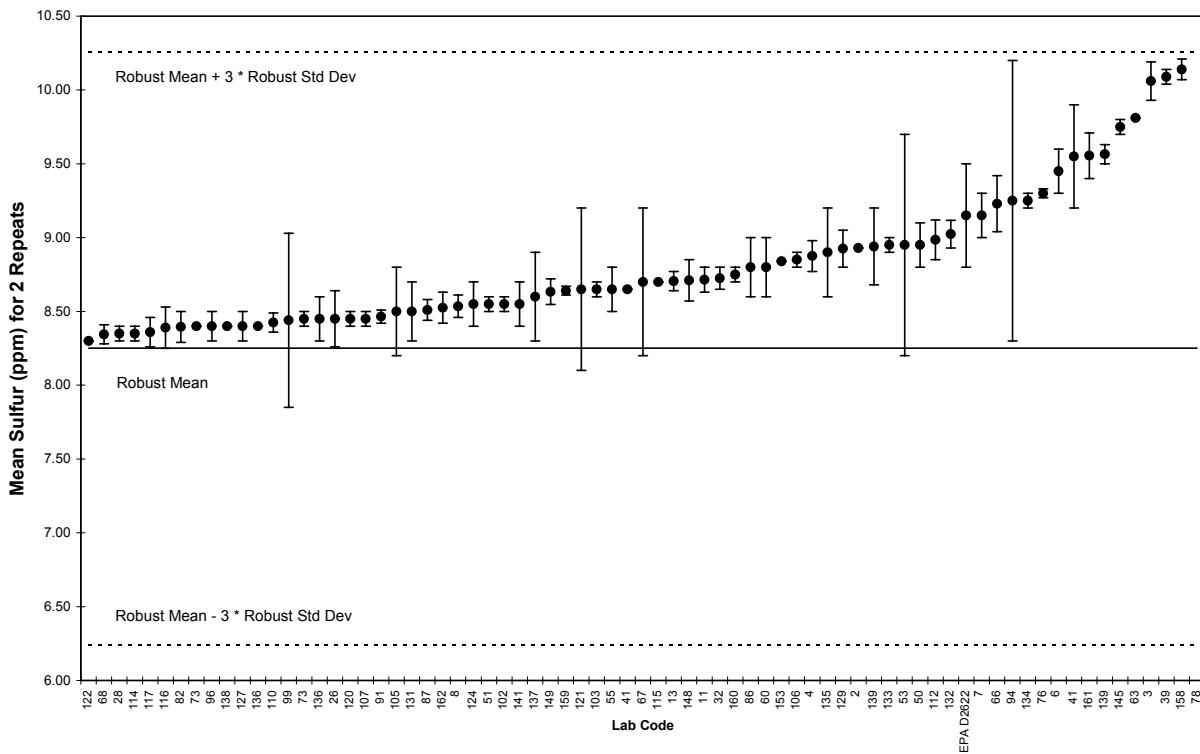

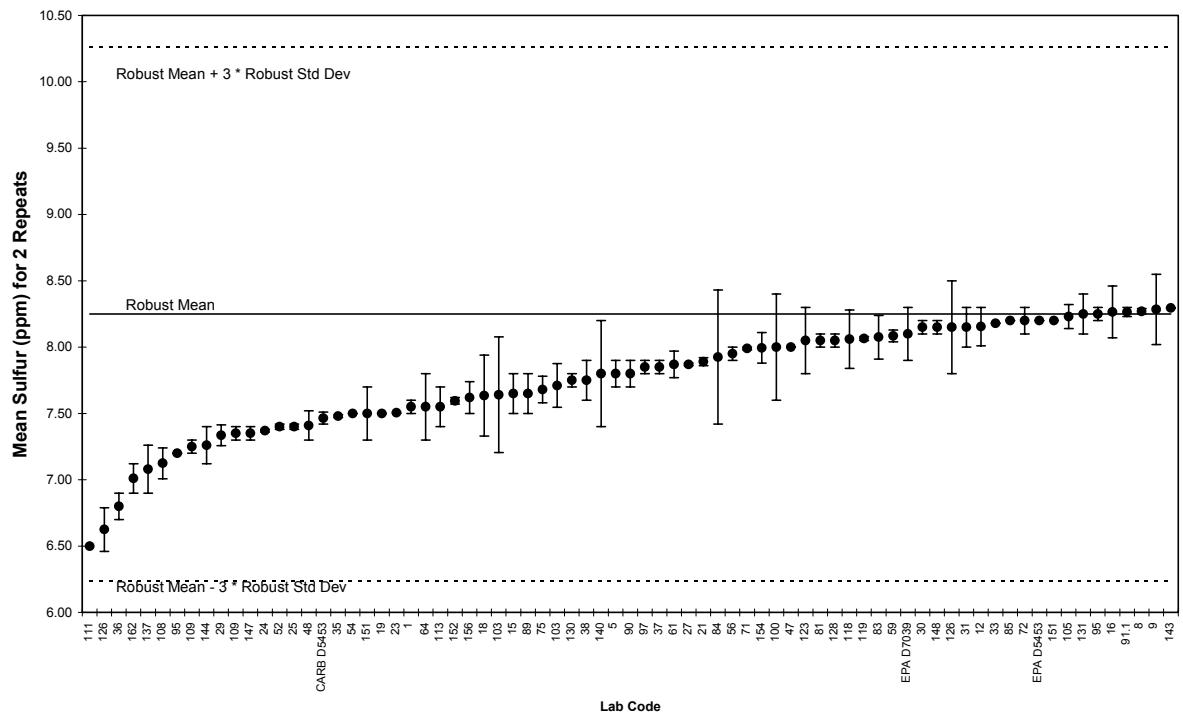

For the July Fuel No. 4 data in Figures 8 and 9, 19 labs had differences in their two sulfur repeat values that exceeded the composite ASTM repeatability value using the In-House calibration. This compares to 27 labs when using the NIST calibration. In addition, the July Fuel No. 4 data for three labs using the In-House method and ten labs using the NIST method were excluded due to having all three repeat values meet the outlier deletion criteria.

For the August Fuel No. 5 in Figures 10 and 11, 15 labs had differences in their two sulfur repeat values that exceeded the composite ASTM repeatability value using the In-House calibration. This compares to 22 labs when using the NIST calibration. In addition, the August Fuel No. 5 data for six labs using the In-House method and seven labs using the NIST method were excluded due to having all three repeat values meet the outlier deletion criteria.

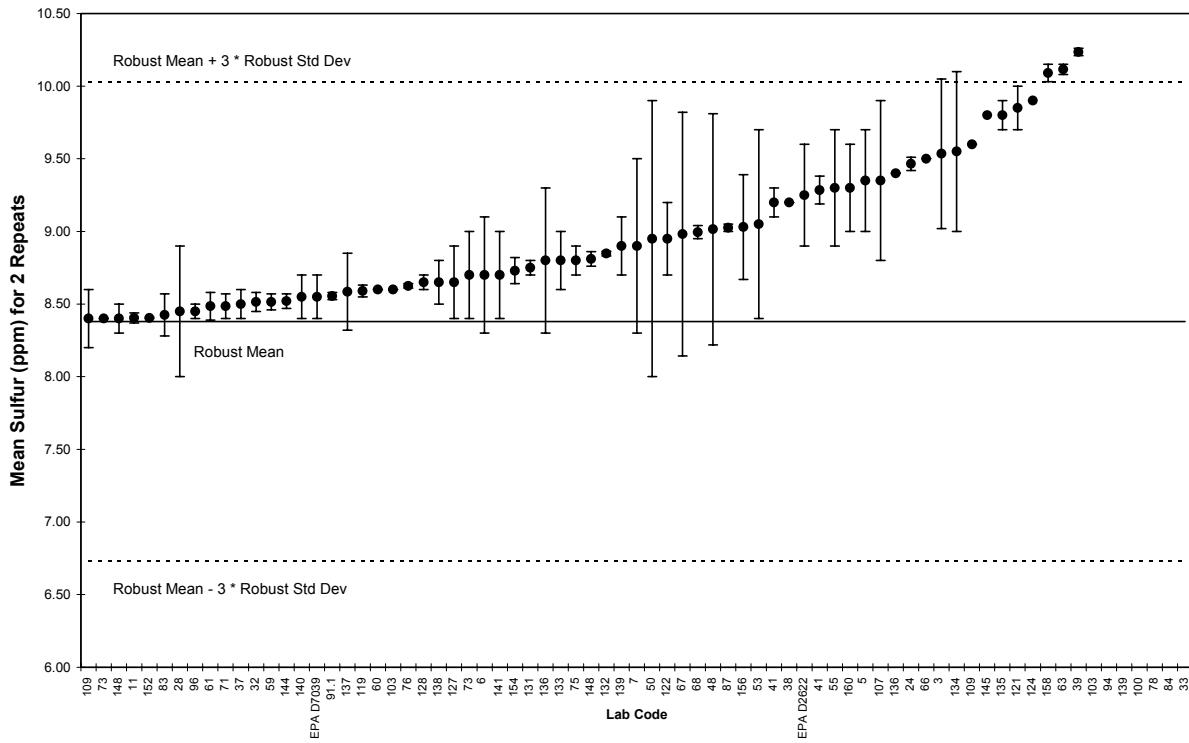

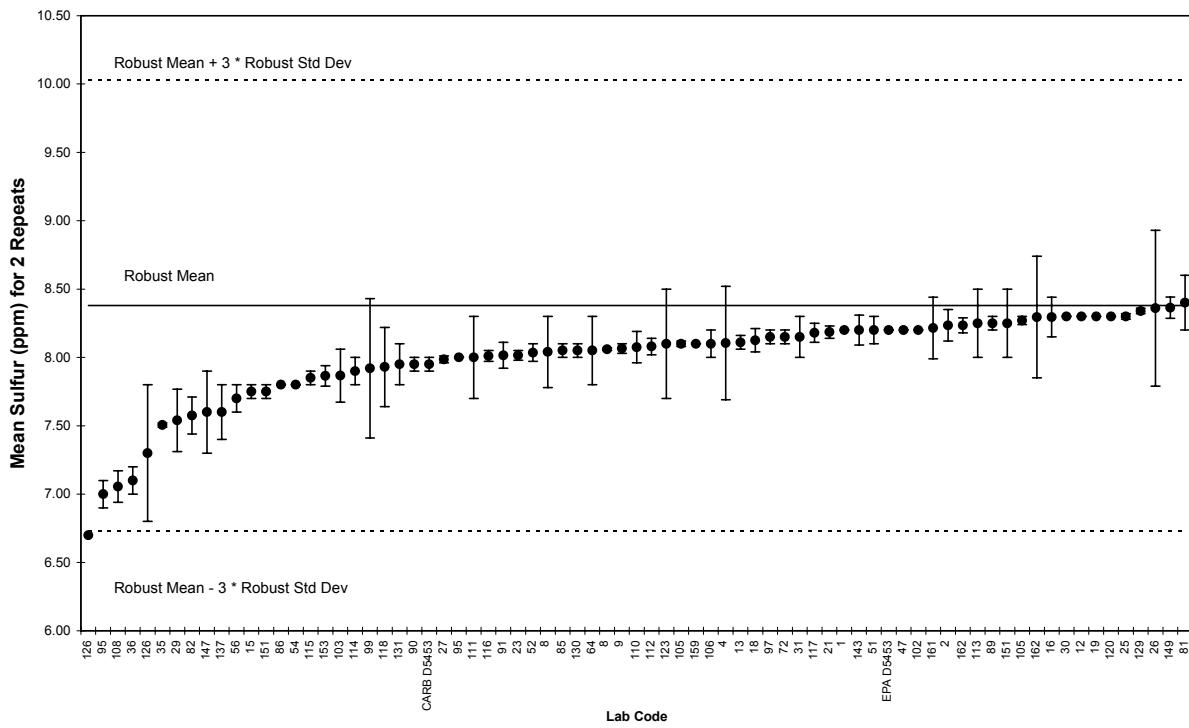

#### **5.4 Comparisons of Lab ASTM Reproducibility**

Figures 12-15 contain plots of composite ASTM lab reproducibility values computed with the robust outlier deletion techniques and ASTM analysis. July Fuel No. 4 and August Fuel No. 5 data are represented for both the in-house and NIST calibration methods.

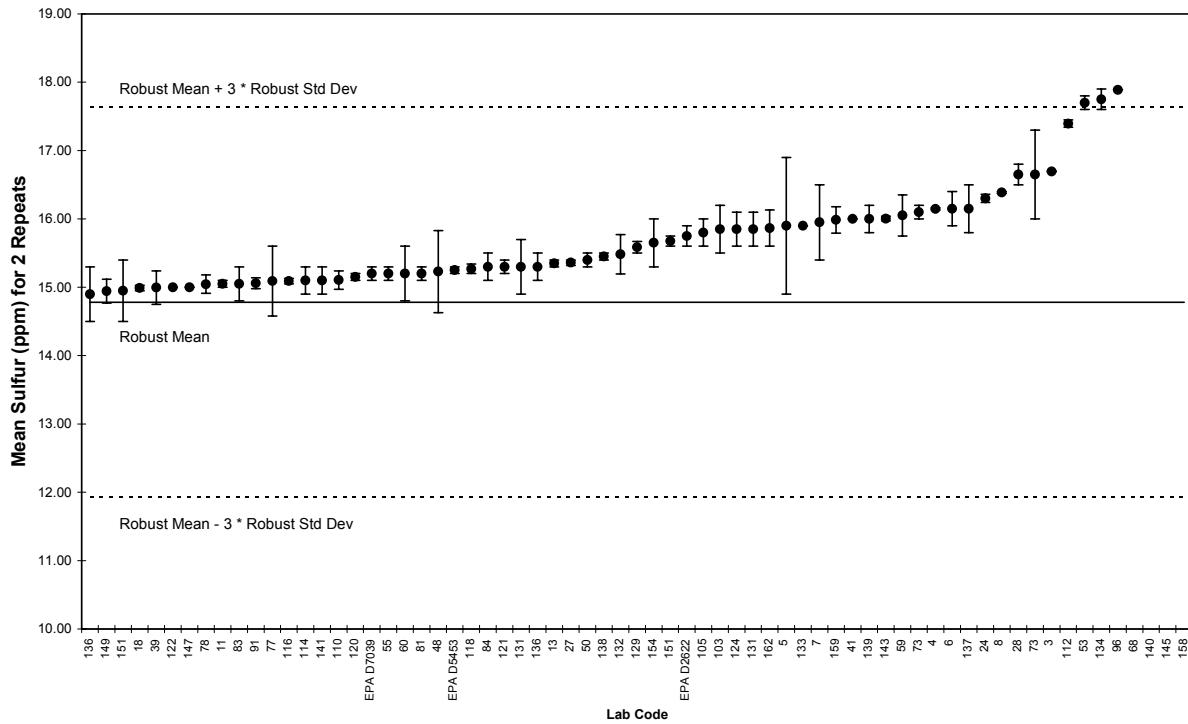

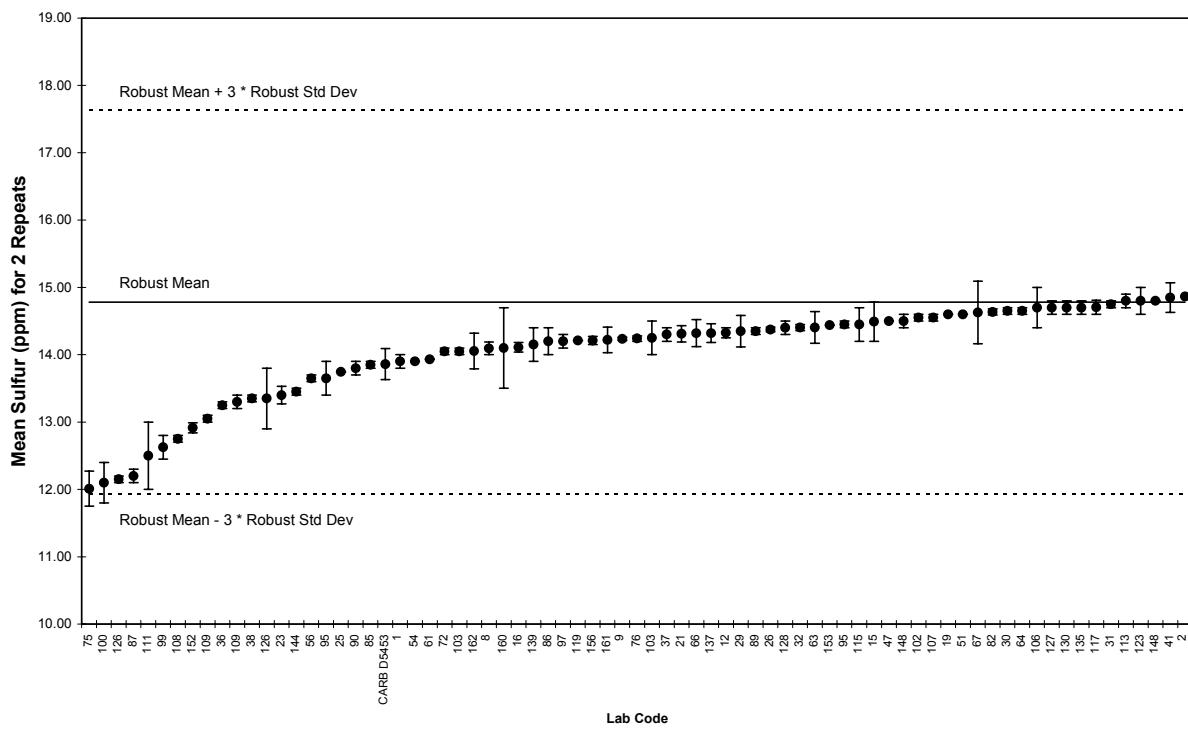

The means of the lab repeat values (including lines extending to the lab repeat min and max values) are plotted against the lab code numbers. Included on the plot is a solid line at the robust mean for the composite data and the dashed lines are the limits at (robust mean)  $+/-3 \times$  (robust standard deviation). The plot allows one to compare the deviation between the lab mean and the robust mean to the upper and lower limits. Lab means that exceed the limits are readily identified. In addition, the code numbers of the labs that were deleted in the outlier checks are listed in the figure. Note also that the code numbers for the EPA and CARB labs have been replaced with their abbreviated titles, namely EPA and CARB along with the corresponding test number. Some lab codes may occur multiple times, if they qualified multiple instruments.

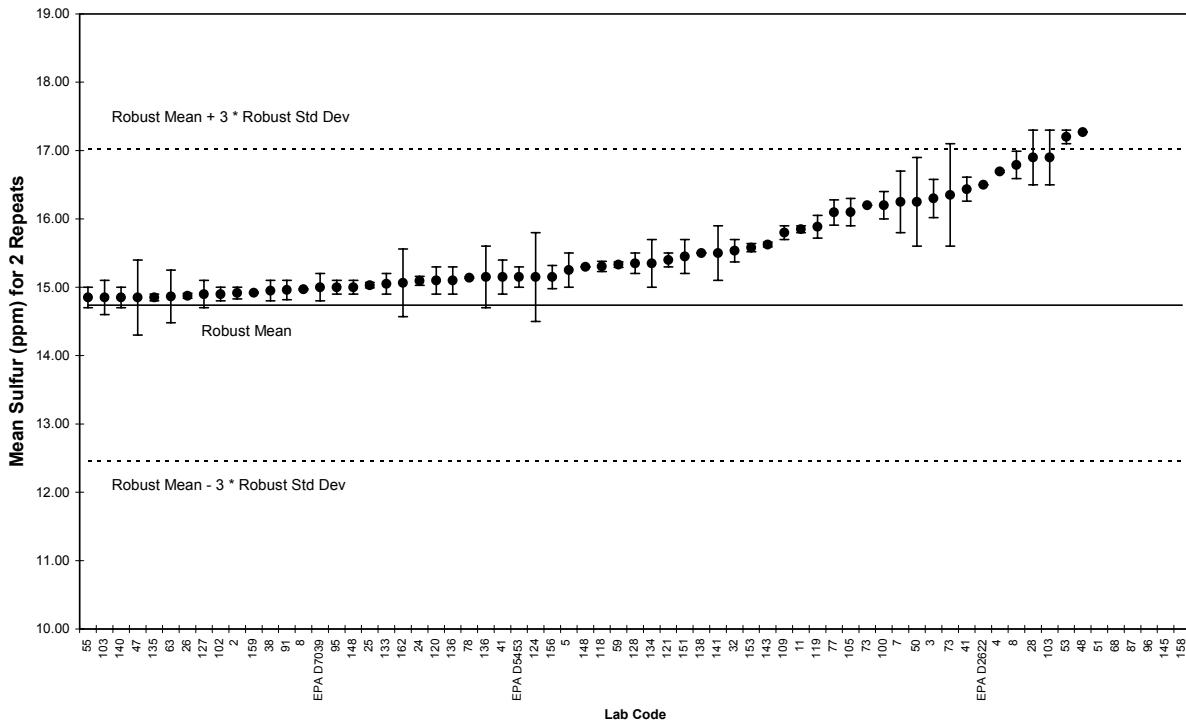

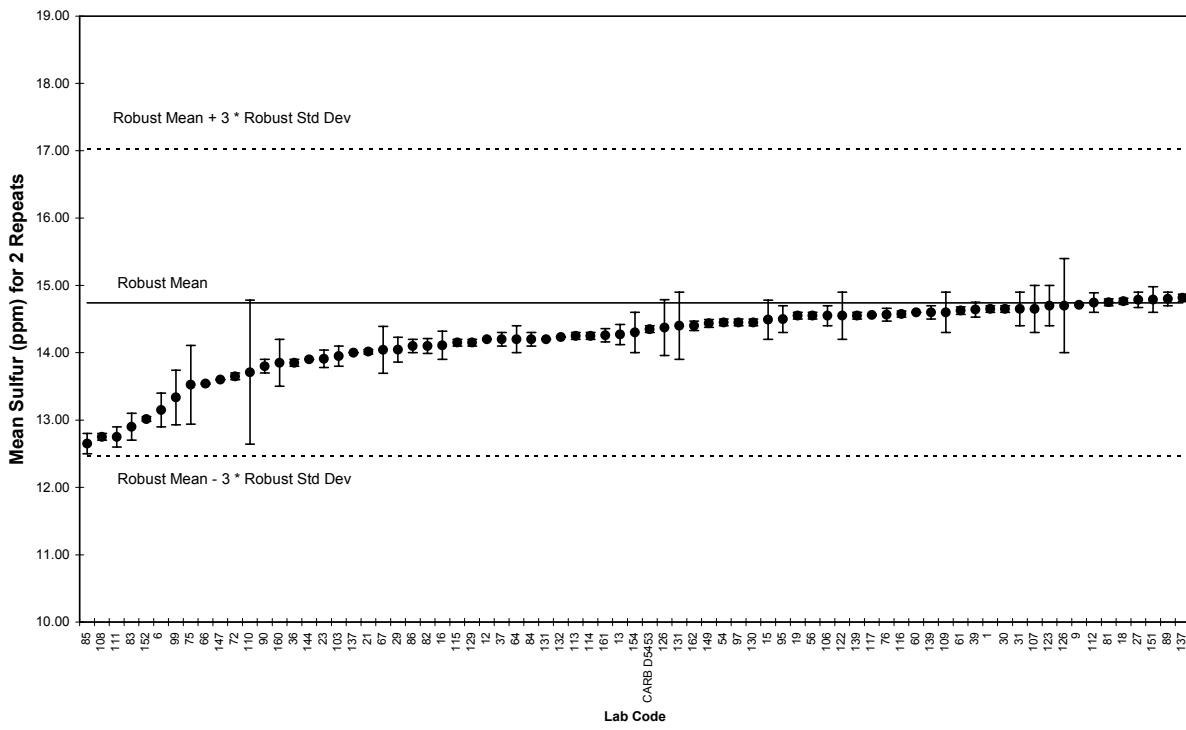

**Figure 12. Plot of Lab Mean vs. Lab Code for Composite Data for July Fuel No. 4 With Robust Outlier Deletion, In-House Calibration, and ASTM Analysis**

**Figure 13. Plot of Lab Mean vs. Lab Code for Composite Data for July Fuel No. 4 With Robust Outlier Deletion, NIST Calibration, and ASTM Analysis**

**Figure 14. Plot of Lab Mean vs. Lab Code for Composite Data for August Fuel No. 5 With Robust Outlier Deletion, In-House Calibration, and ASTM Analysis**

**Figure 15. Plot of Lab Mean vs. Lab Code for Composite Data for August Fuel No. 5 With Robust Outlier Deletion, NIST Calibration, and ASTM Analysis**

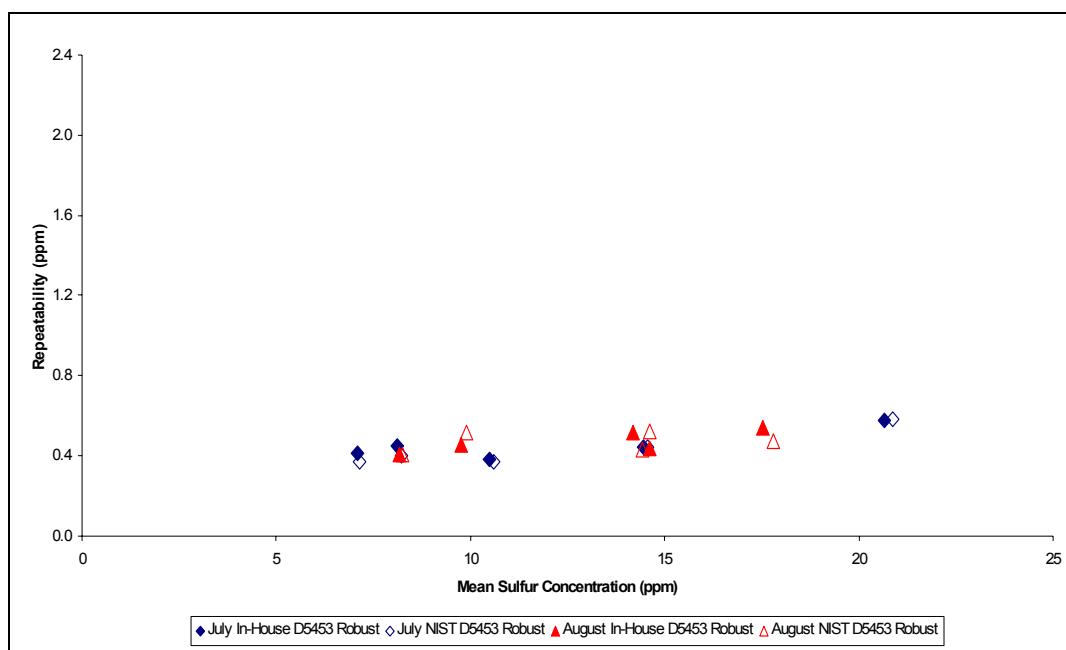

For the July Fuel No. 4 data in Figures 12 and 13, no labs had means of their two sulfur repeat values that exceeded the robust mean limits using the In-House calibration. This compares to four labs exceeding the limits when using the NIST calibration. In addition, the July Fuel No. 4 data for one lab using the In-House method and seven labs using the NIST method were excluded due to having all three repeat values meet the outlier deletion criteria.

For the August Fuel No. 5 data in Figures 14 and 15, three labs had means of their two sulfur repeat values that exceeded the robust mean limits using the In-House calibration. This compares to two labs exceeding the limits when using the NIST calibration. In addition, the August Fuel No. 5 data for four labs using the In-House method and six labs using the NIST method were excluded due to having all three repeat values meet the outlier deletion criteria.

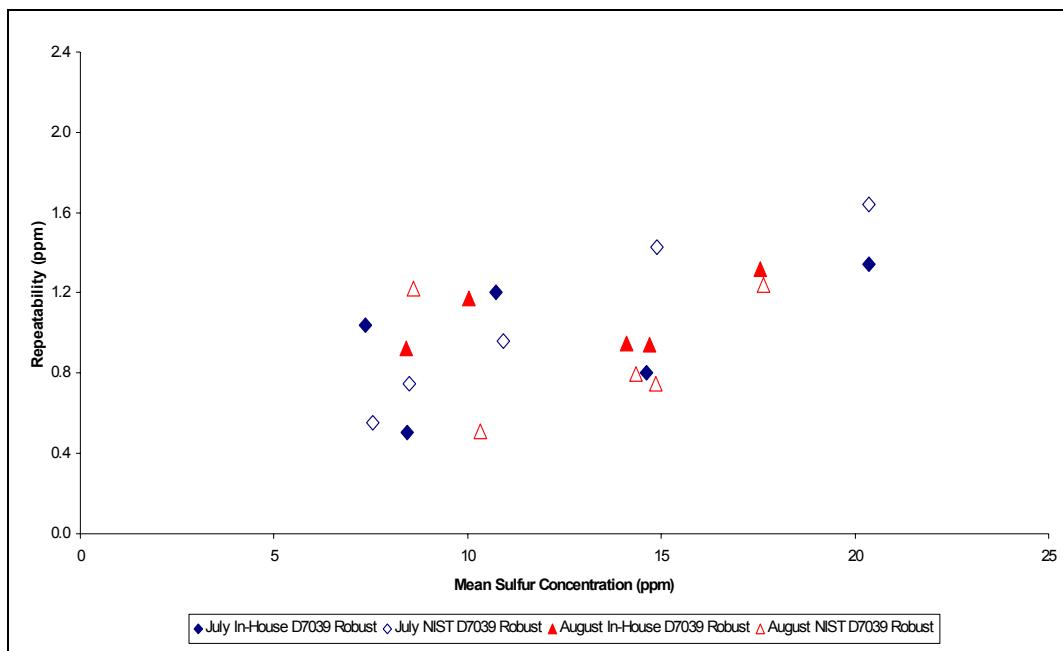

Additional plots of lab reproducibility are contained in Appendix D. Included are plots for the July No. 4 and August No. 5 test fuels for the composite test methods by deletion method, calibration type, and analysis method.

## 5.5 Comparisons of Overall ASTM Repeatability by Test Method

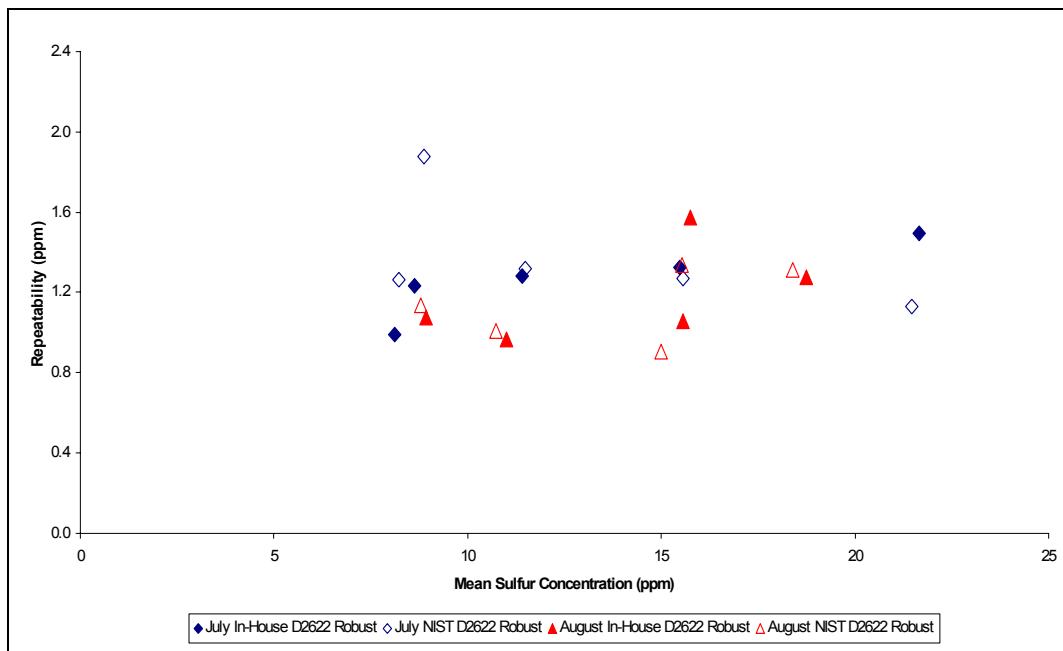

Figures 16-20 contain plots of the ASTM repeatability values against the mean sulfur data for all ten fuels with the robust outlier deletion method and categorized by the In-House and NIST calibration methods. The plots are listed by test method: D 5453 in Figure 16, D 7039 in Figure 17, D 2622 in Figure 18, EDXRF in Figure 19, and the Composite in Figure 20. Figures 21-23 contain similar plots of the repeatability values for D 5453, D 2622 and D 7039, but include for comparison the 2004-05 ASTM Crosscheck repeatability values.

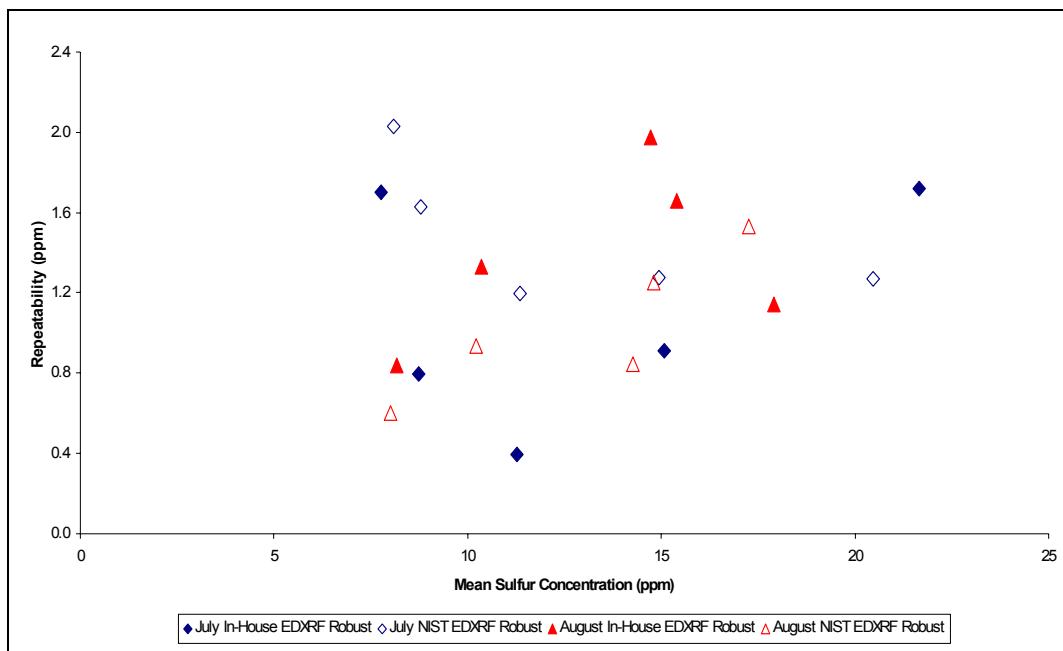

**Figure 16. Plot of ASTM Repeatability vs. Mean Sulfur for D 5453 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

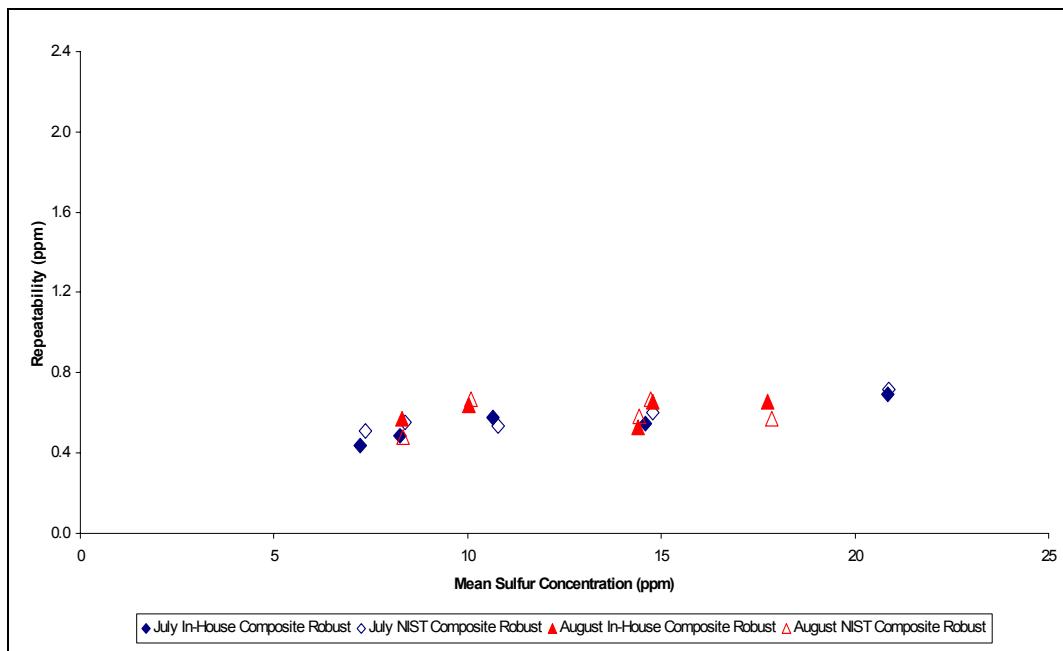

**Figure 17. Plot of ASTM Repeatability vs. Mean Sulfur for D 7039 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

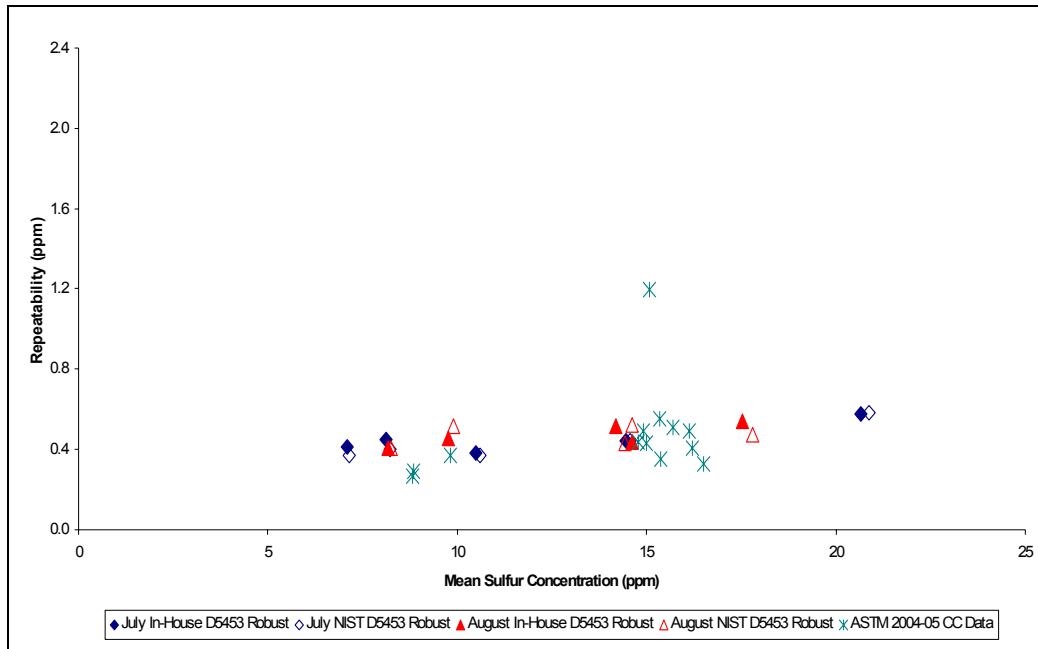

**Figure 18. Plot of ASTM Repeatability vs. Mean Sulfur for D 2622 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

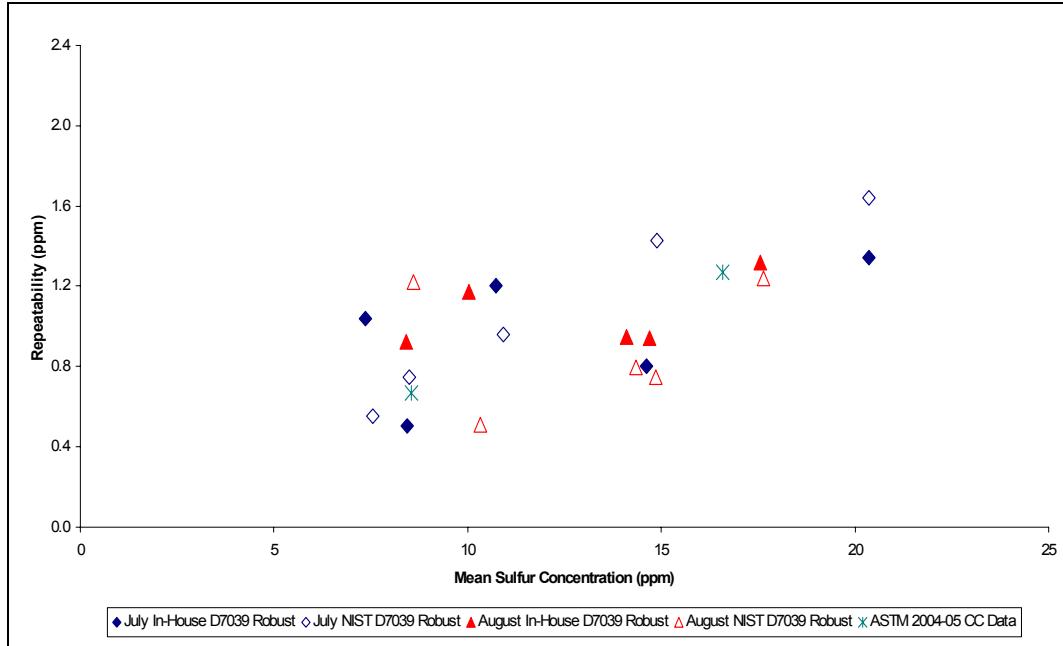

**Figure 19. Plot of ASTM Repeatability vs. Mean Sulfur for EDXRF Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

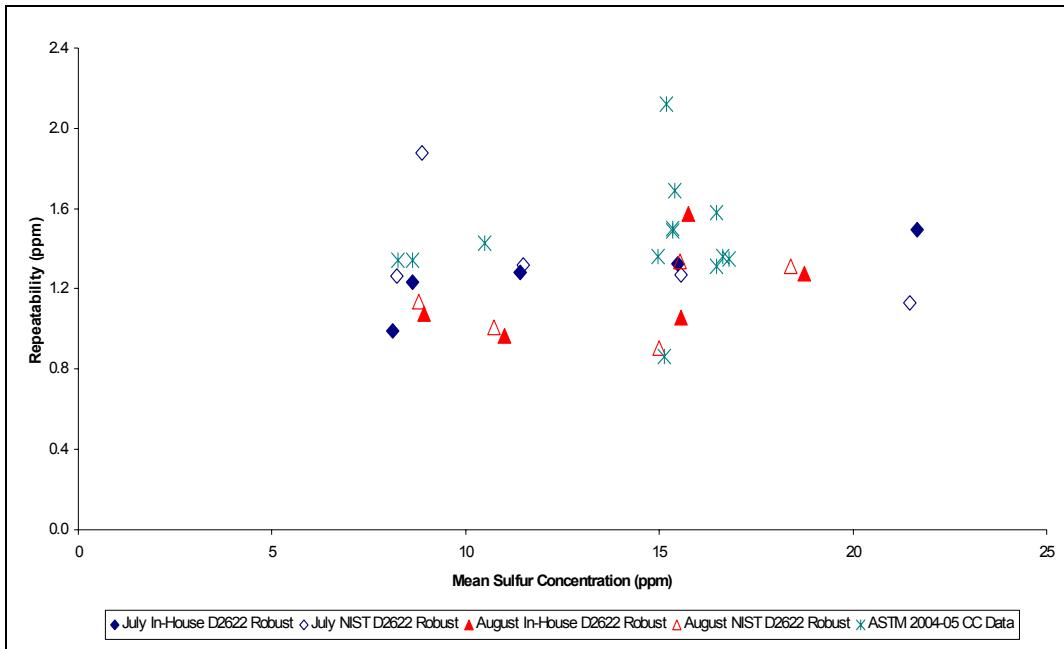

**Figure 20. Plot of ASTM Repeatability vs. Mean Sulfur for Composite Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

**Figure 21. Plot of ASTM Repeatability vs. Mean Sulfur for D 5453 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration – Added ASTM 2004-05 Crosscheck Data**

**Figure 22. Plot of ASTM Repeatability vs. Mean Sulfur for D 7039 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration – Added ASTM 2004-05 Crosscheck Data**

**Figure 23. Plot of ASTM Repeatability vs. Mean Sulfur for D 2622 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration – Added ASTM 2004-05 Crosscheck Data**

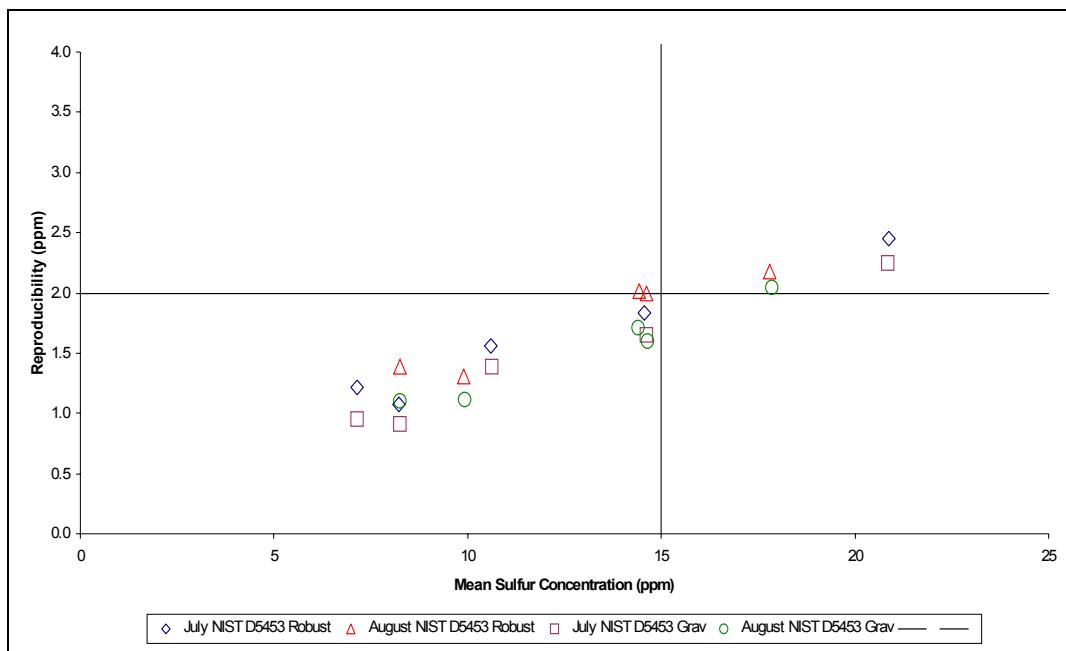

There were no noticeable differences among the repeatability values in Figures 16-20 across the two calibration methods. The smallest r-values and the smallest variation occurred in Figure 16 when using D 5453. The D 7039 and D 2622 values were in the middle with the D 7039 values in Figure 17 being slightly smaller and less variable than the D 2622 values in Figure 18, but larger than the D 5453 values in Figure 16. The largest r-values and largest variation occurred using EDXRF in Figure 19. This variation is possibly a result of the small number of labs (six) using this procedure. The 2004-05 ASTM CC r-values were generally in agreement with these results except for one larger CC r-value that occurred in comparisons using D 5453 in Figure 21, and one larger value that occurred in comparisons using D 2622 in Figure 23.

Additional plots of lab repeatability are contained in Appendix E. Included are plots for the ASTM analysis for each test method, calibration method, and outlier deletion method.

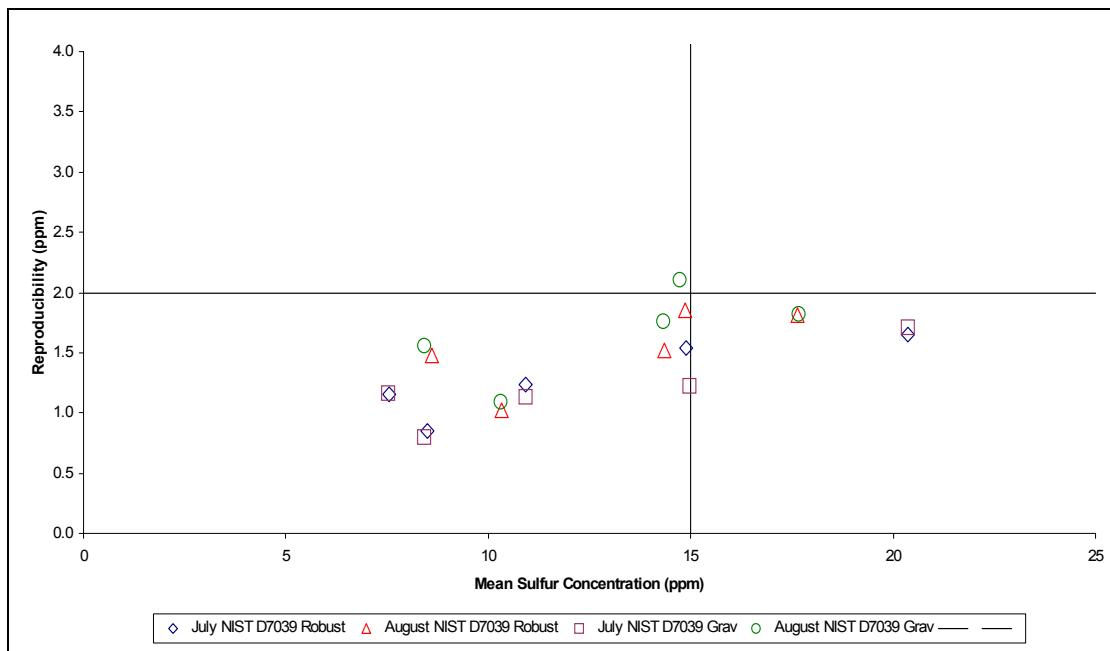

## 5.6 Comparisons of Overall Reproducibility by Test Method

### 5.6.1 Robust vs. Gravimetric Deletion

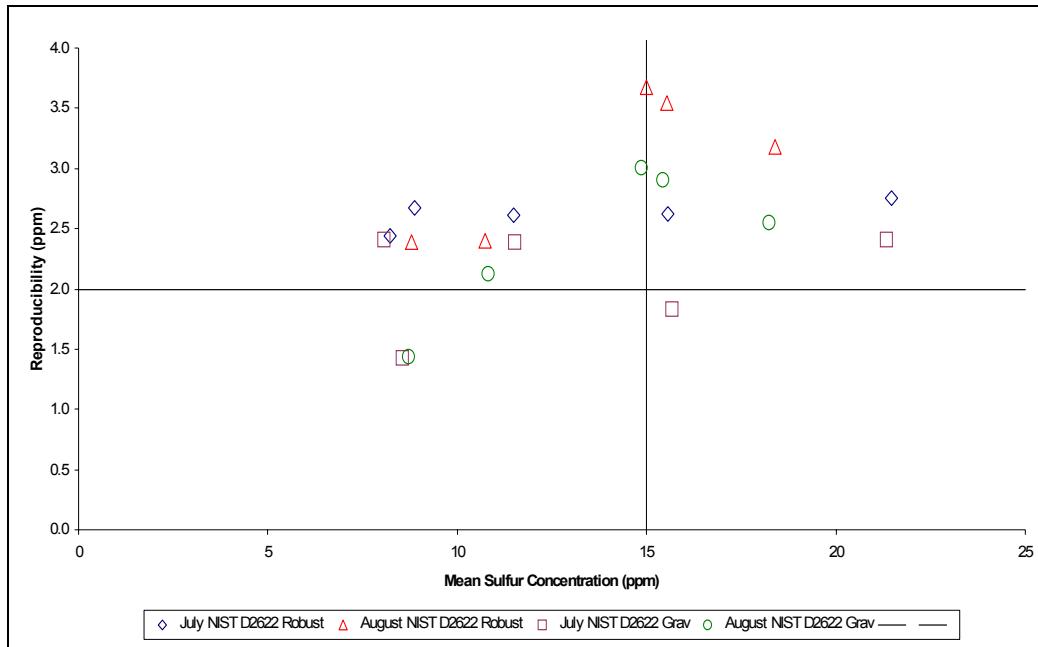

Figures 24-28 contain plots of ASTM reproducibility values versus the mean sulfur for all ten fuels with the NIST calibration and categorized by the robust and gravimetric outlier deletion methods. The figures are listed in order by test method: D 5453, D 7039, D 2622, EDXRF and Composite.

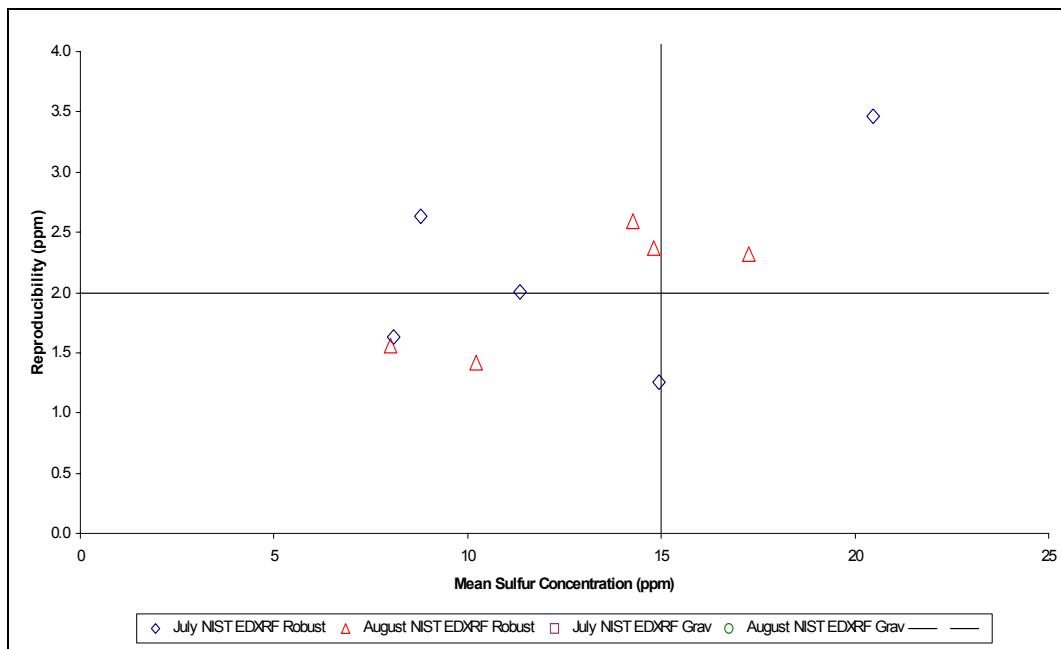

**Figure 24. Plot of ASTM Reproducibility vs. Mean Sulfur for D 5453 Data With NIST Calibration, and Categorized by Robust and Gravimetric Outlier Deletion**

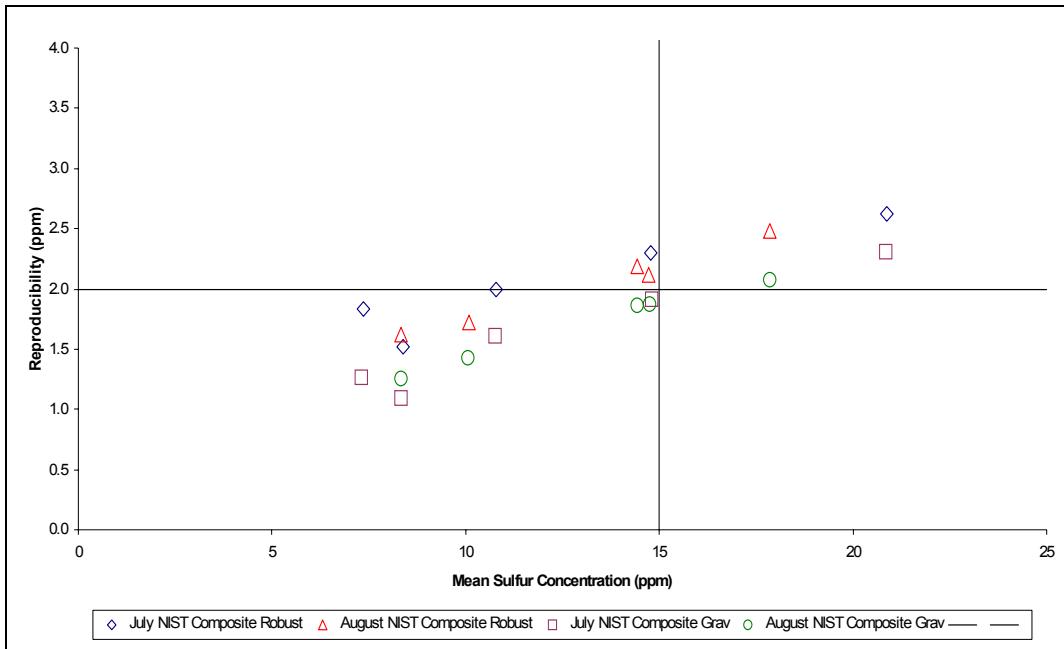

**Figure 25. Plot of ASTM Reproducibility vs. Mean Sulfur for D 7039 Data With NIST Calibration, and Categorized by Robust and Gravimetric Outlier Deletion**

**Figure 26. Plot of ASTM Reproducibility vs. Mean Sulfur for D 2622 Data With NIST Calibration, and Categorized by Robust and Gravimetric Outlier Deletion**

**Figure 27. Plot of ASTM Reproducibility vs. Mean Sulfur for EDXRF Data With NIST Calibration, and Categorized by Robust and Gravimetric Outlier Deletion**

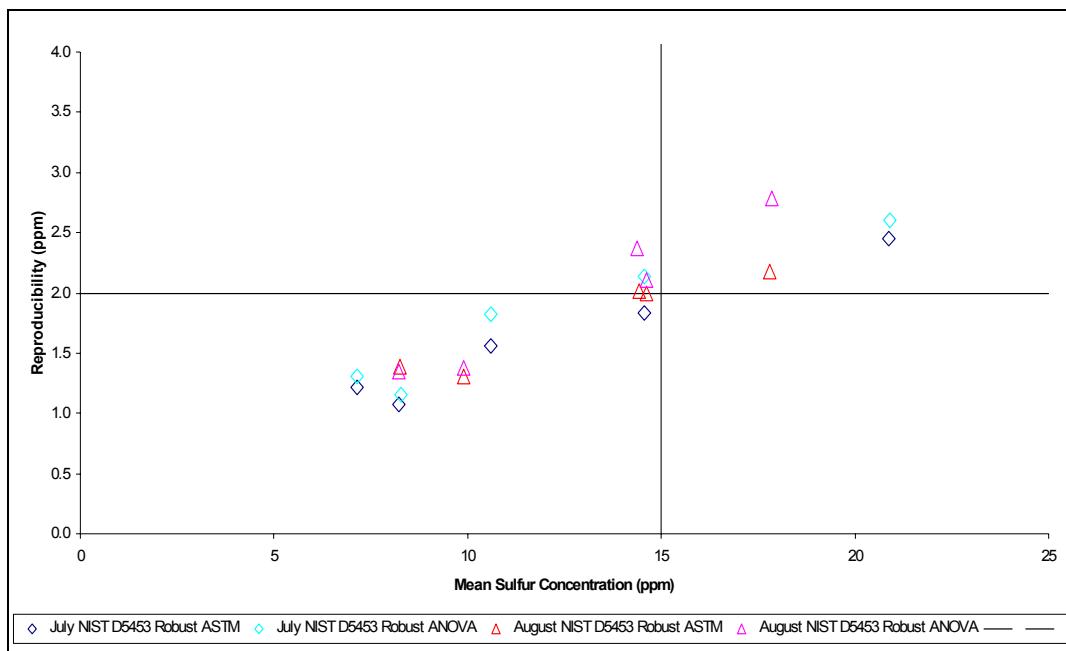

**Figure 28. Plot of ASTM Reproducibility vs. Mean Sulfur for Composite Data With NIST Calibration, and Categorized by Robust and Gravimetric Outlier Deletion**

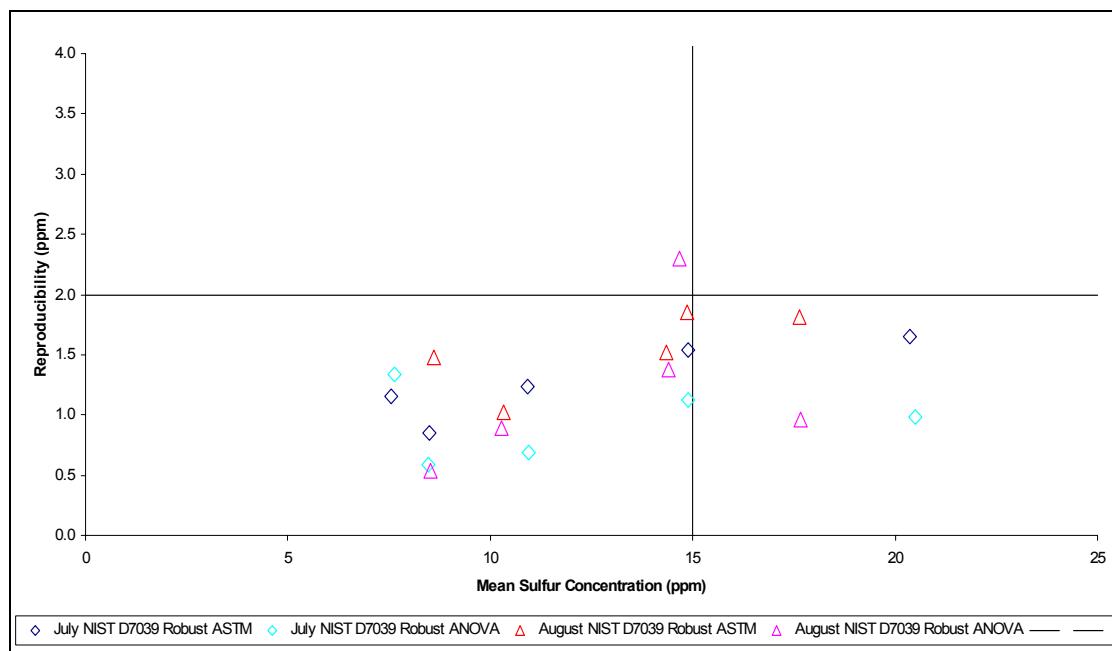

For both D 5453 and D 7039, when using the NIST calibration, the R-values for gravimetric outlier deletion are smaller than those for robust outlier deletion. The R-values for D 2622 and EDXRF have more scatter and no clear trends.

#### 5.6.2 ASTM vs. ANOVA Using NIST Calibration

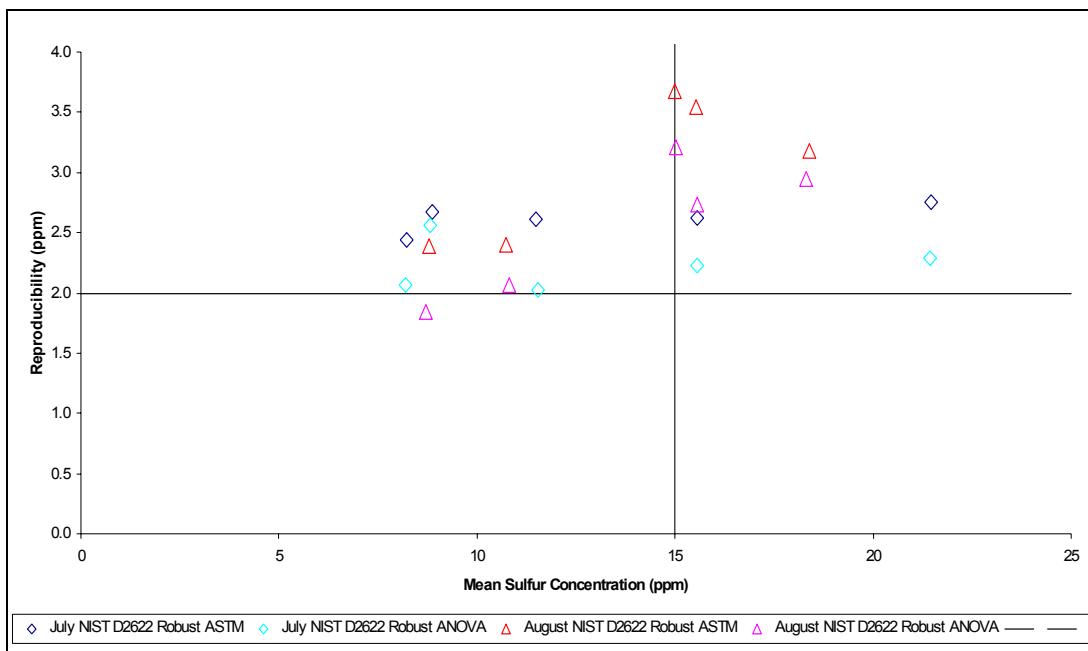

Figures 29-33 contain plots of overall reproducibility values versus the mean sulfur for all ten fuels, with the NIST calibration and robust outlier deletion, and categorized by the ASTM and ANOVA methods. The figures are listed in order by test method: D 5453, D 7039, D 2622, EDXRF and Composite.

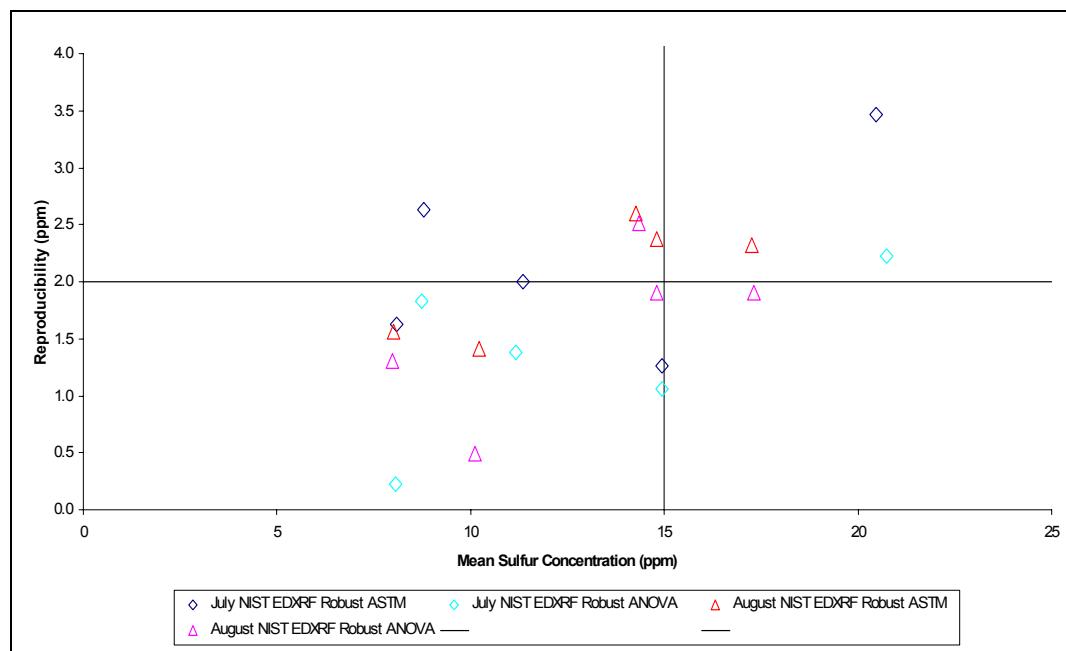

**Figure 29. Plot of Reproducibility vs. Mean Sulfur for D 5453 Data With NIST Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

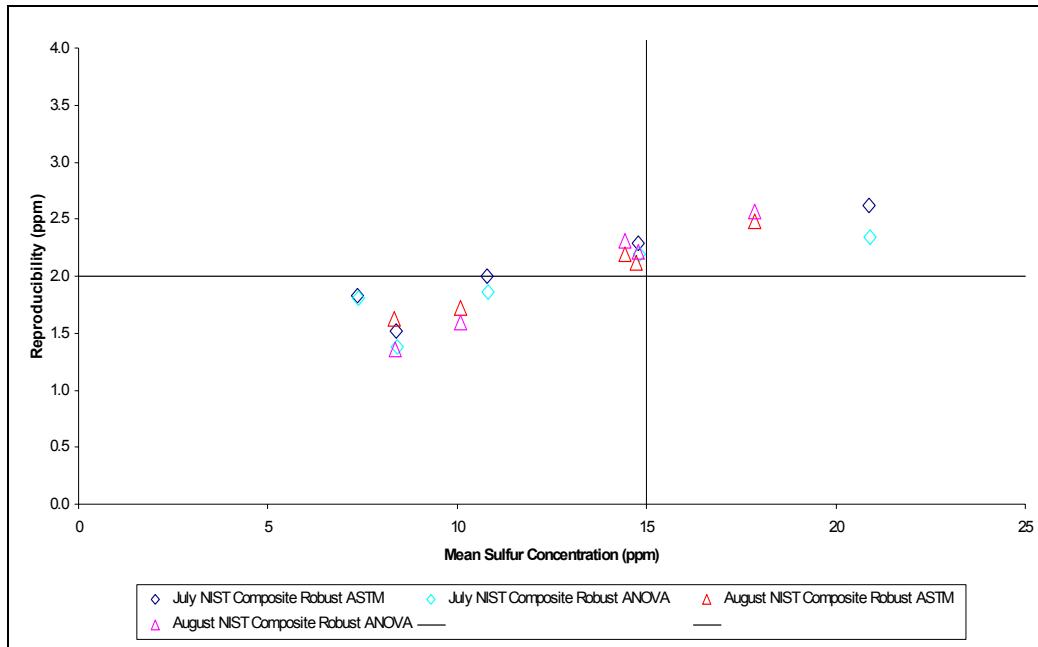

**Figure 30. Plot of Reproducibility vs. Mean Sulfur for D 7039 Data With NIST Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

**Figure 31. Plot of Reproducibility vs. Mean Sulfur for D 2622 Data With NIST Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

**Figure 32. Plot of Reproducibility vs. Mean Sulfur for EDXRF Data With NIST Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

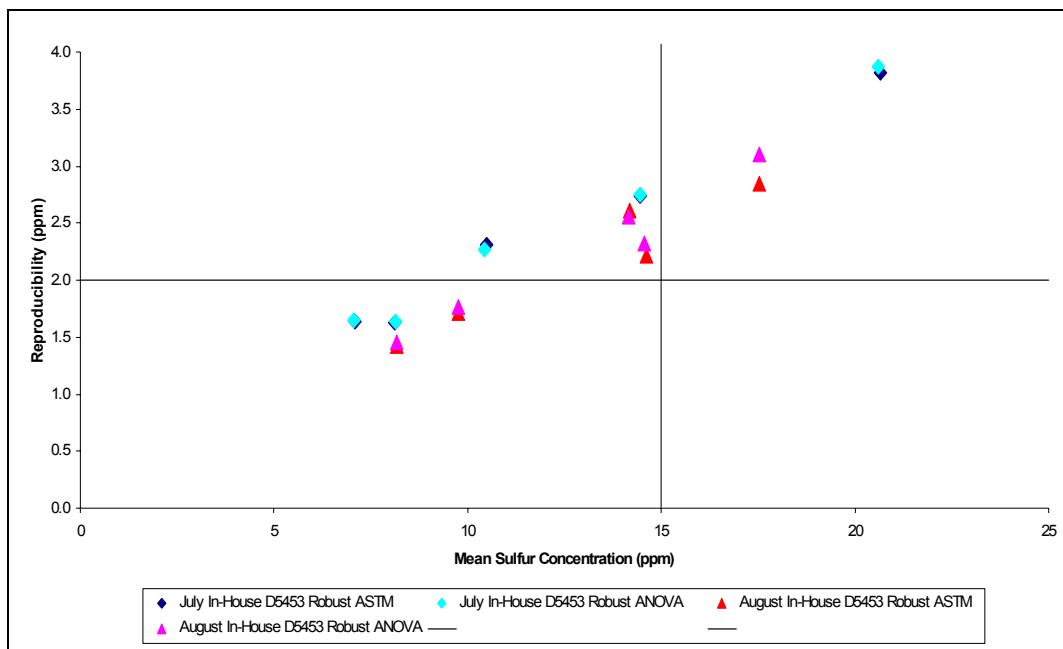

**Figure 33. Plot of Reproducibility vs. Mean Sulfur for Composite Data With NIST Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

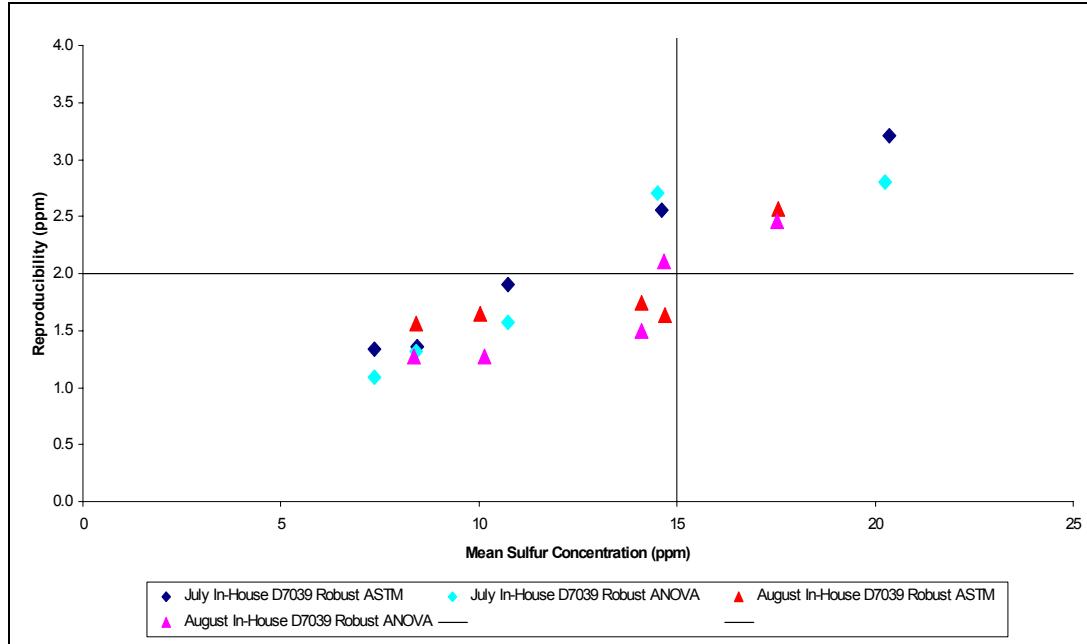

For D 5453 in Figure 29, the R-values for the ASTM method are equal to or smaller than the R-values for the ANOVA method with the NIST calibration. In contrast, for D 7039, D 2622, and EDXRF in Figures 30-32 the R-values for the ANOVA method are generally smaller than the R-values for the ASTM method when using the NIST calibration.

#### 5.6.3 ASTM vs. ANOVA Using In-House Calibration

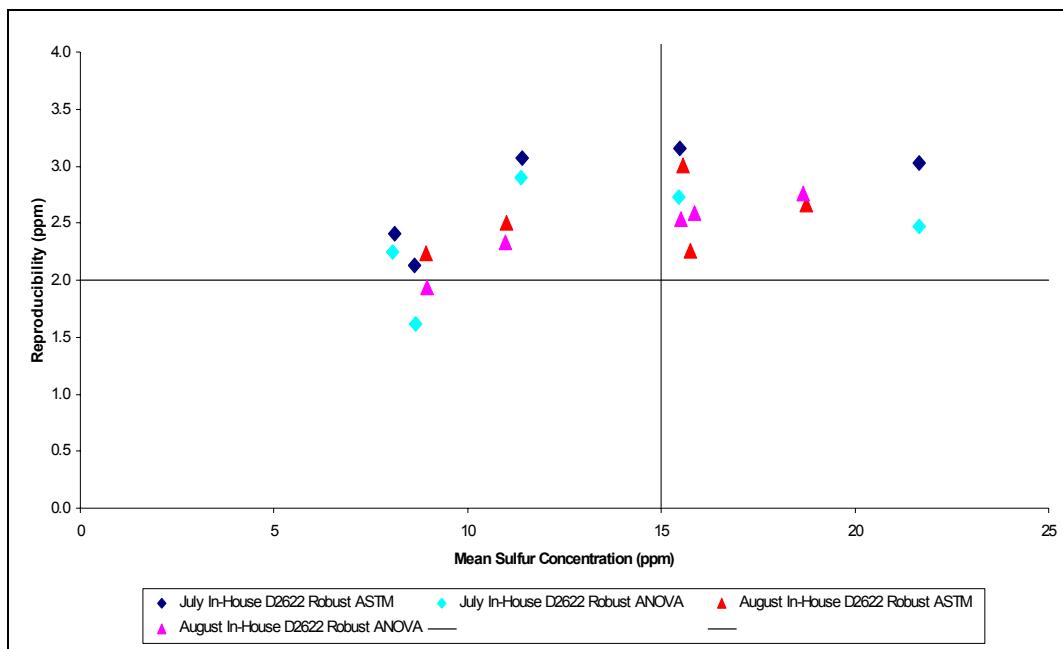

Figures 34-38 contain plots of overall reproducibility values versus the mean sulfur for all ten fuels, with the In-House calibration and robust outlier deletion, and categorized by the ASTM and ANOVA methods. The figures are listed in order by test method: D 5453, D 7039, D 2622, EDXRF and Composite.

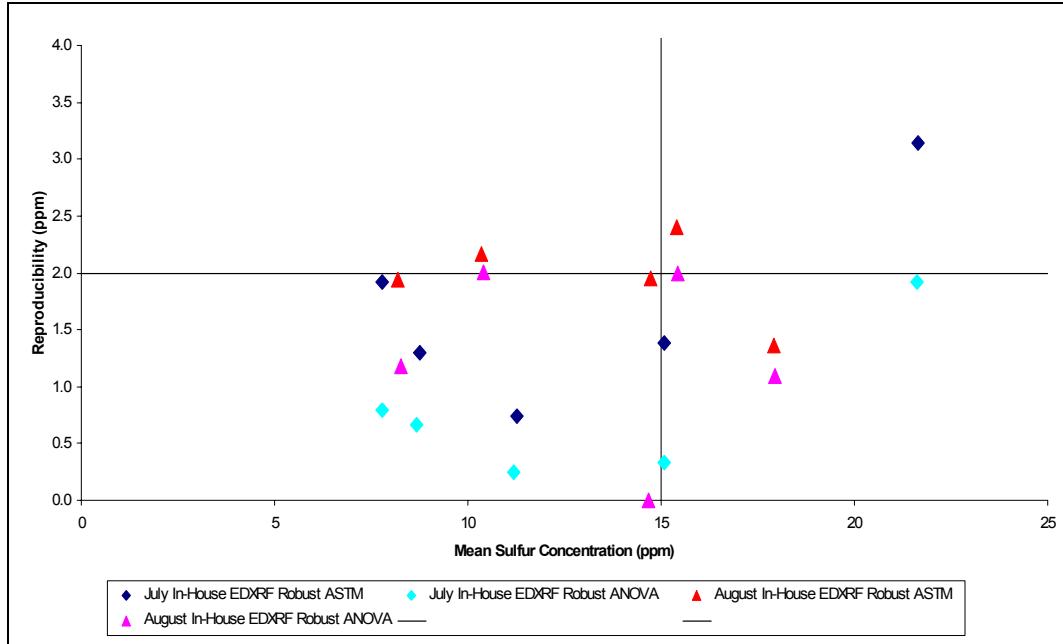

**Figure 34. Plot of Reproducibility vs. Mean Sulfur for D 5453 Data With In-House Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

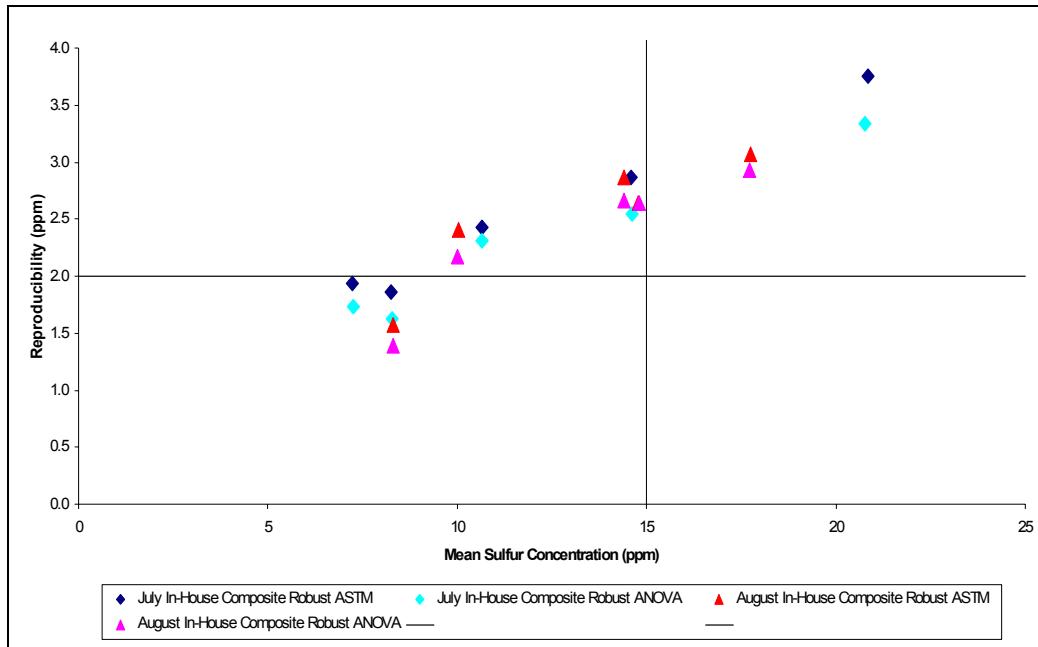

**Figure 35. Plot of Reproducibility vs. Mean Sulfur for D 7039 Data With In-House Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

**Figure 36. Plot of Reproducibility vs. Mean Sulfur for D 2622 Data With In-House Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

**Figure 37. Plot of Reproducibility vs. Mean Sulfur for EDXRF Data With In-House Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

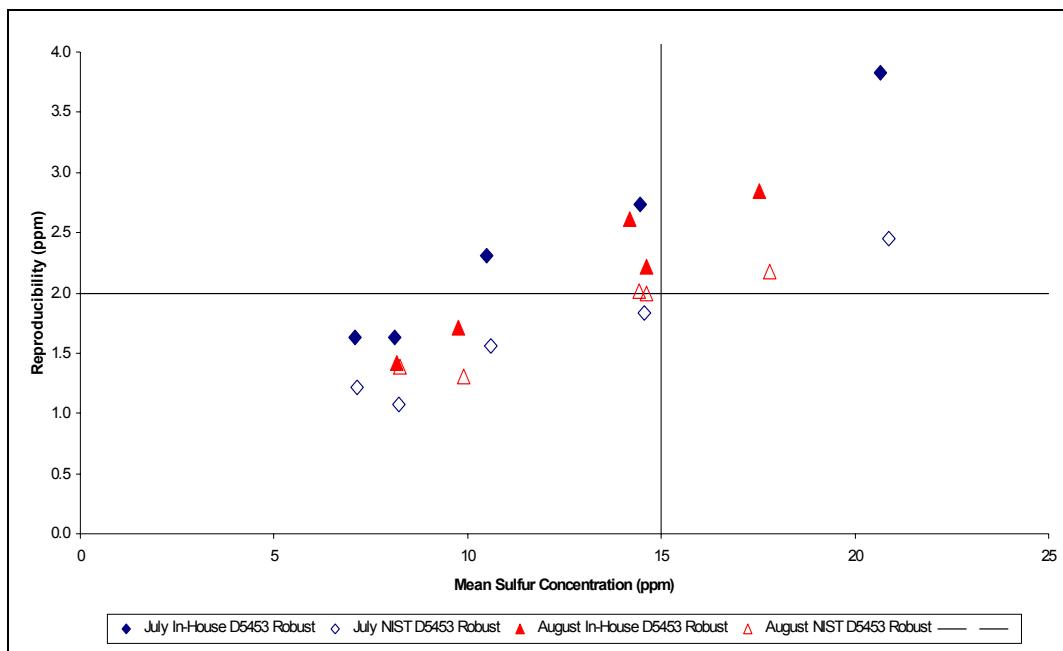

**Figure 38. Plot of Reproducibility vs. Mean Sulfur for Composite Data With In-House Calibration and Robust Outlier Deletion, and Categorized by ASTM and ANOVA Analysis Methods**

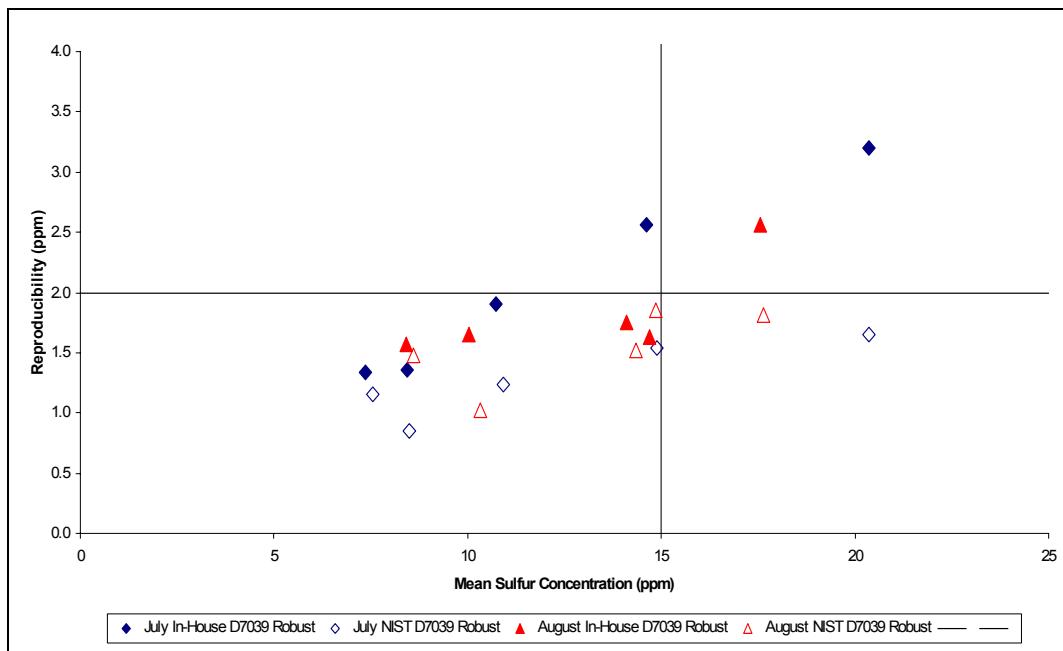

For D 5453 in Figure 34, there is no clear advantage between the R-values for the ASTM and ANOVA methods with the In-House calibration. In contrast, for D 7039, D 2622, and EDXRF in Figures 35-37 the R-values for the ANOVA method are generally smaller than the R-values for the ASTM method with the In-House calibration.

#### 5.6.4 In-House vs. NIST Calibration

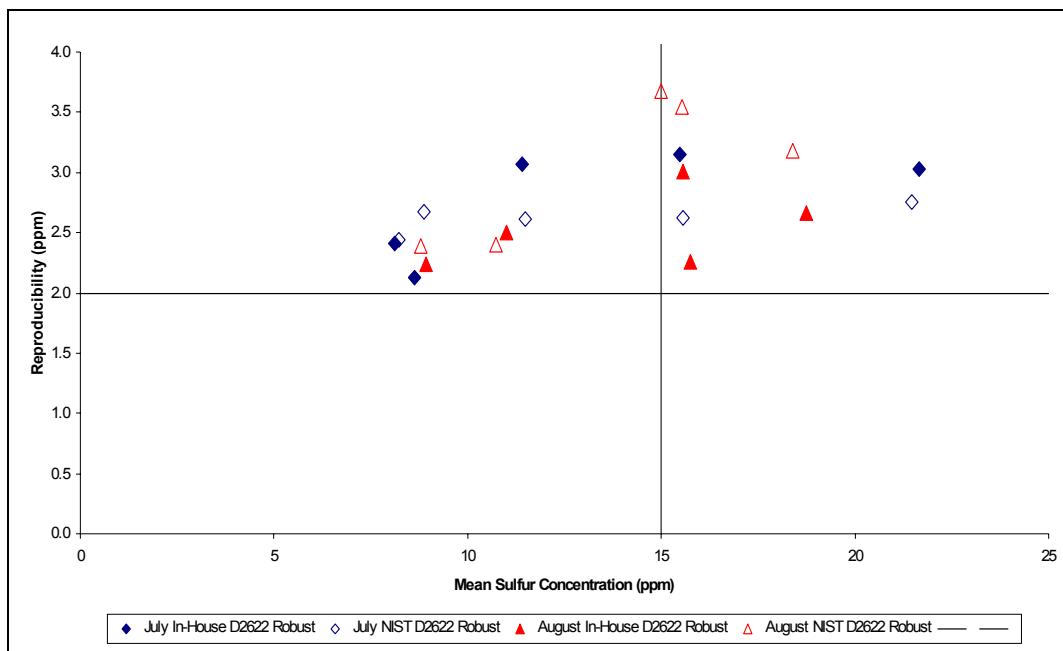

Figures 39-43 contain plots of the ASTM reproducibility values against the mean sulfur data for all ten fuels, with the robust outlier deletion method and categorized by the In-House and NIST calibration methods. The figures are listed in order by test method: D 5453, D 7039, D 2622, EDXRF and Composite. Figures 44-46 contain similar plots of the reproducibility values for D 5453, D 2622 and D 7039, but include for comparison the 2004-05 ASTM CC reproducibility values.

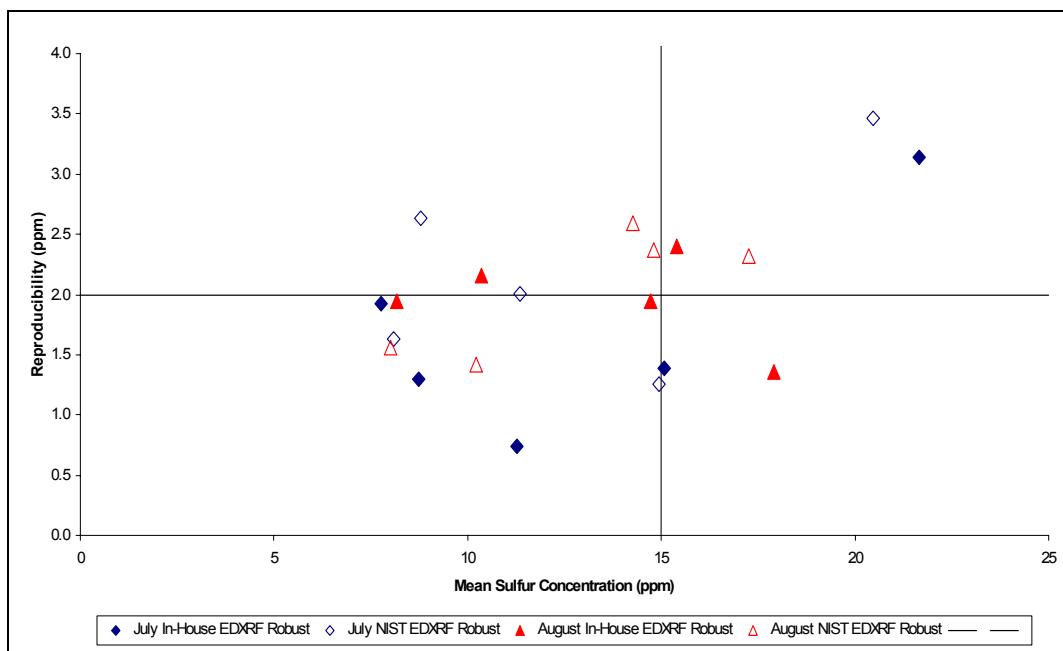

**Figure 39. Plot of ASTM Reproducibility vs. Mean Sulfur for D 5453 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

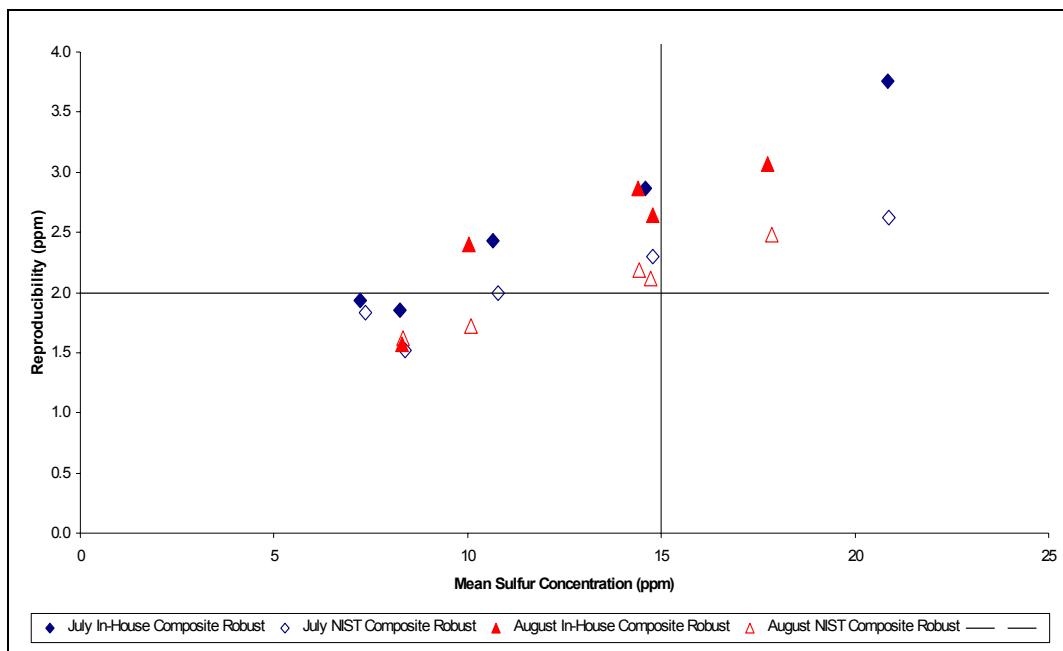

**Figure 40. Plot of ASTM Reproducibility vs. Mean Sulfur for D 7039 With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

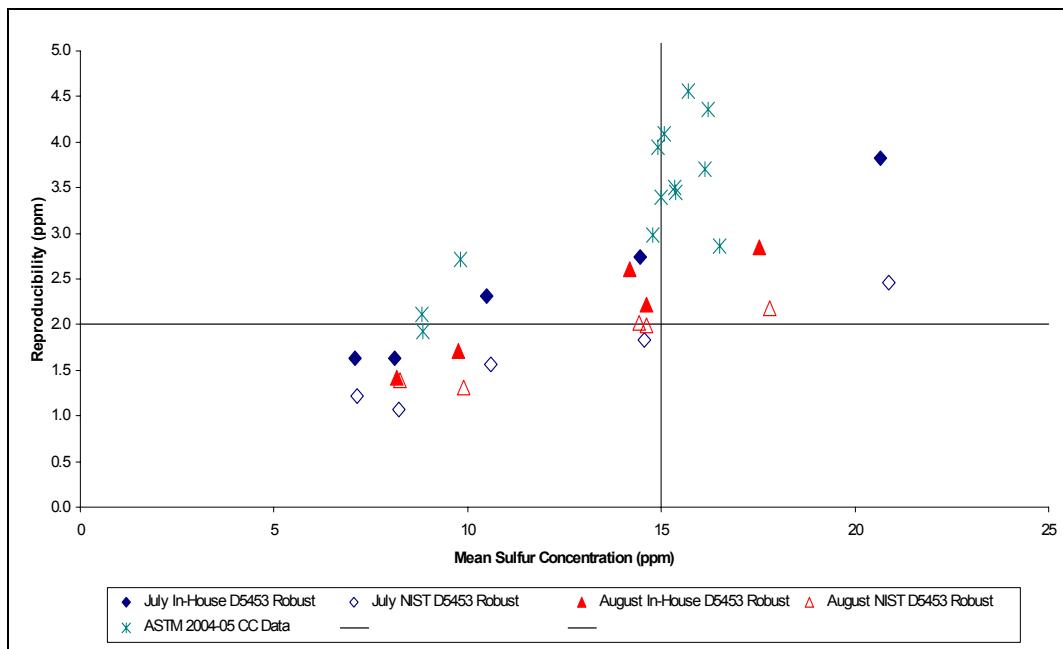

**Figure 41. Plot of ASTM Reproducibility vs. Mean Sulfur for D 2622 With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

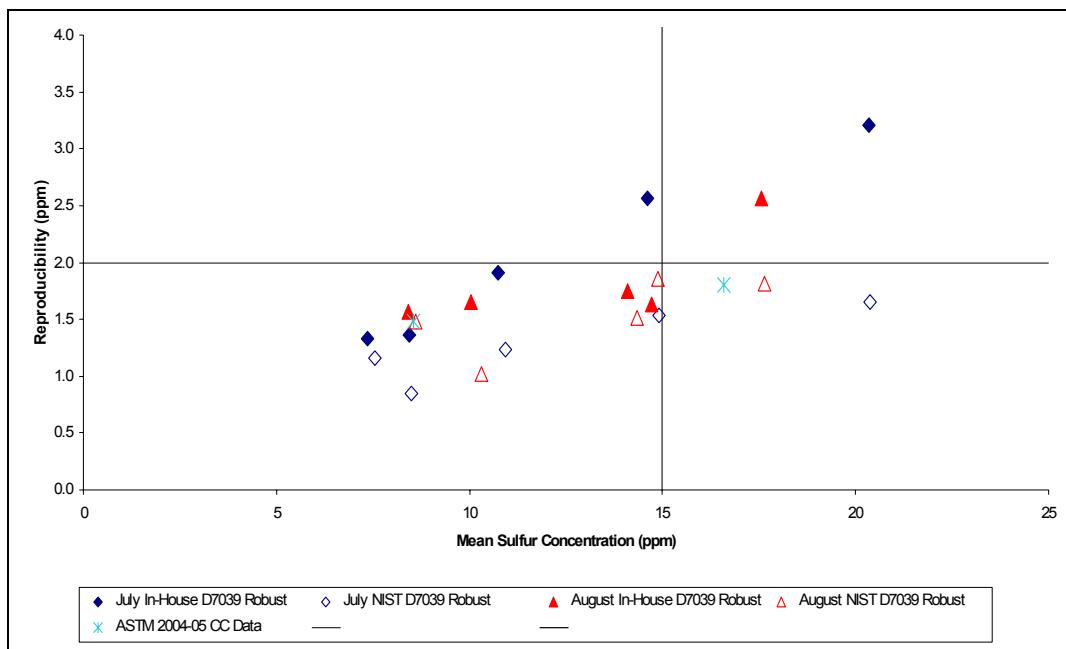

**Figure 42. Plot of ASTM Reproducibility vs. Mean Sulfur for EDXRF Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

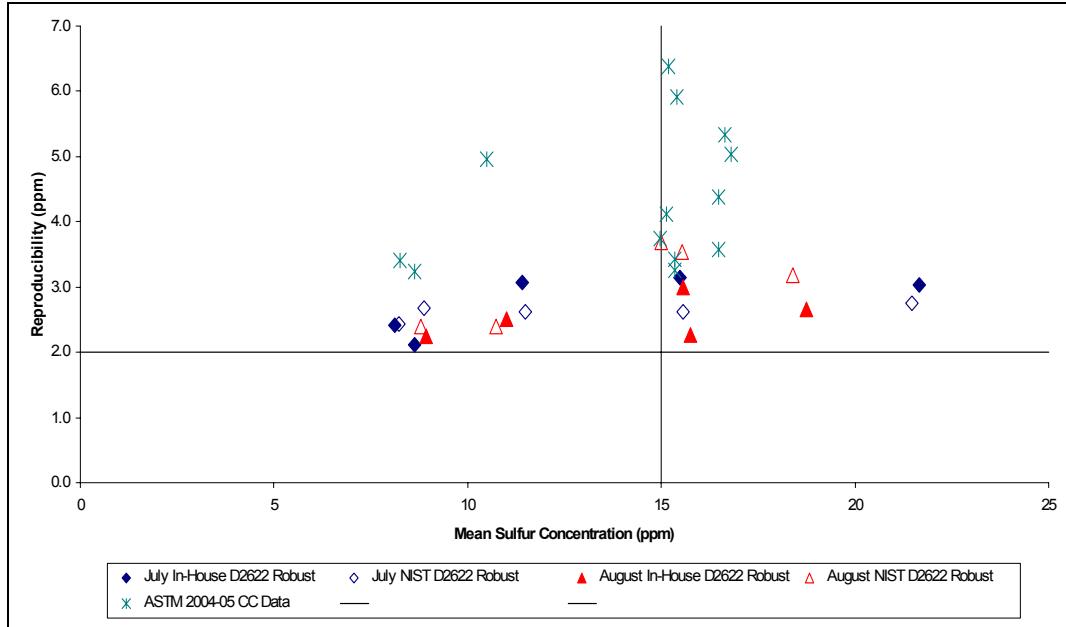

**Figure 43. Plot of ASTM Reproducibility vs. Mean Sulfur for Composite Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration**

**Figure 44. Plot of ASTM Reproducibility vs. Mean Sulfur for D 5453 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration - Added ASTM 2004-05 Crosscheck Data**

**Figure 45. Plot of ASTM Reproducibility vs. Mean Sulfur for D 7039 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration - Added ASTM 2004-05 Crosscheck Data**

**Figure 46. Plot of ASTM Reproducibility vs. Mean Sulfur for D 2622 Data With Robust Outlier Deletion, and Categorized by In-House and NIST Calibration - Added ASTM 2004-05 Crosscheck Data**

Test method D 7039 has the lowest R-values followed closely by D 5453. Both have lower R-values with the NIST calibrations than with the In-House calibrations. The R-values for D 2622 are the largest and have much scatter with neither calibration method being better. The R-values for EDXRF have the largest scatter and demonstrate no clear preferences for a calibration method. The R-values are smaller relative to the 2004-05 ASTM CC data for D 5453 and D 2622 data, but similar for D 7039 data. This holds true for both calibration methods.

### 5.6.5 Overall Reproducibility

Some overall trends in reproducibility noted from examining Figures 24-46 are given below.

- The gravimetric deletion method produces lower R-values than the ASTM robust deletion method.
- The R-values obtained using NIST calibrations are lower than the R-values obtained using In-House calibrations.
- The R-values for D 5453 and D 7039 are superior to those for D 2622 and EDXRF, though the EDXRF values may be affected by the small sample size.
- The ANOVA method more often produces similar or slightly lower R-values than the ASTM method for D 7039, D 2622, and EDXRF, regardless of the calibration, but the results are mixed for D 5453 with the ASTM method having lower R-values when combined with the NIST calibration.

A more extensive list of plots of overall reproducibility is contained in Appendix E. Included are plots for each test method, calibration method, deletion method, and analysis method.

Appendix G contains a summary of the reproducibility and repeatability values by test method, calibration type, outlier deletion method, and analysis method for each of the ten test fuels. Included in the tables are the number of valid results, robust mean, robust standard deviation, reproducibility and repeatability.

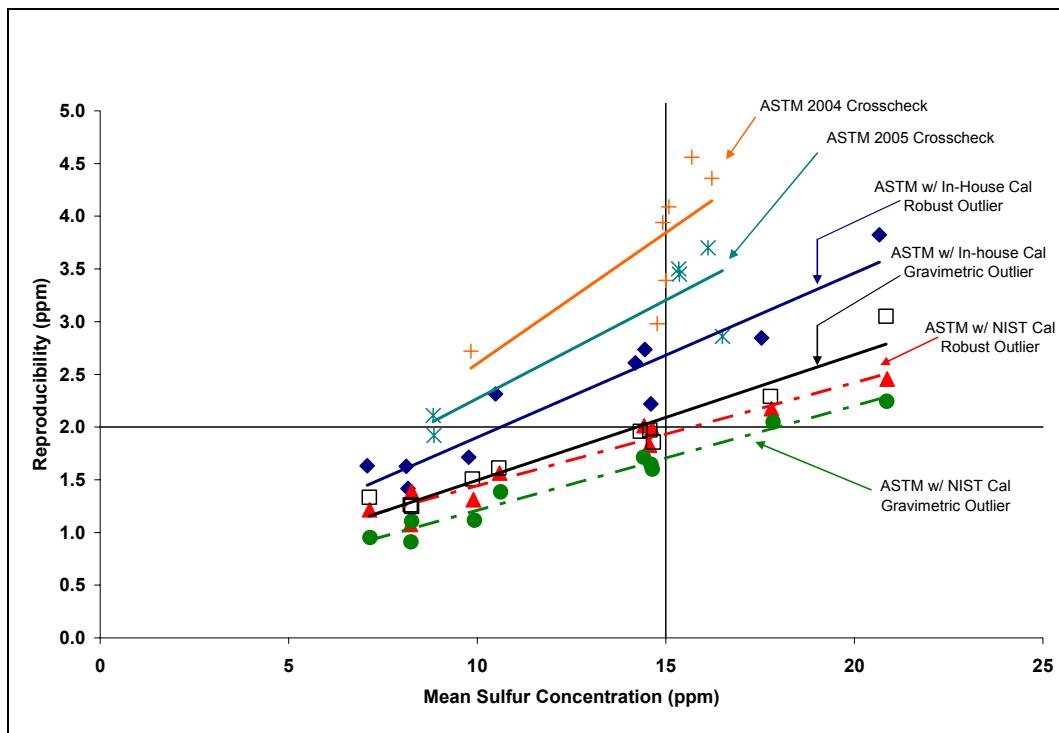

## 5.7 Regression Fits to Reproducibility

The ASTM CC R-values for 2004 and 2005 were compared to the ASTM and ANOVA R-values with both calibration types and outlier deletion methods obtained in this EPA Round-Robin (RR) program. The ASTM CC data are valid for sulfur concentrations greater than 8 ppm, so the lower range on the sulfur concentration is comparable to the fuel range of the EPA RR study. Also, the ASTM CC R-values were computed using the ASTM method.

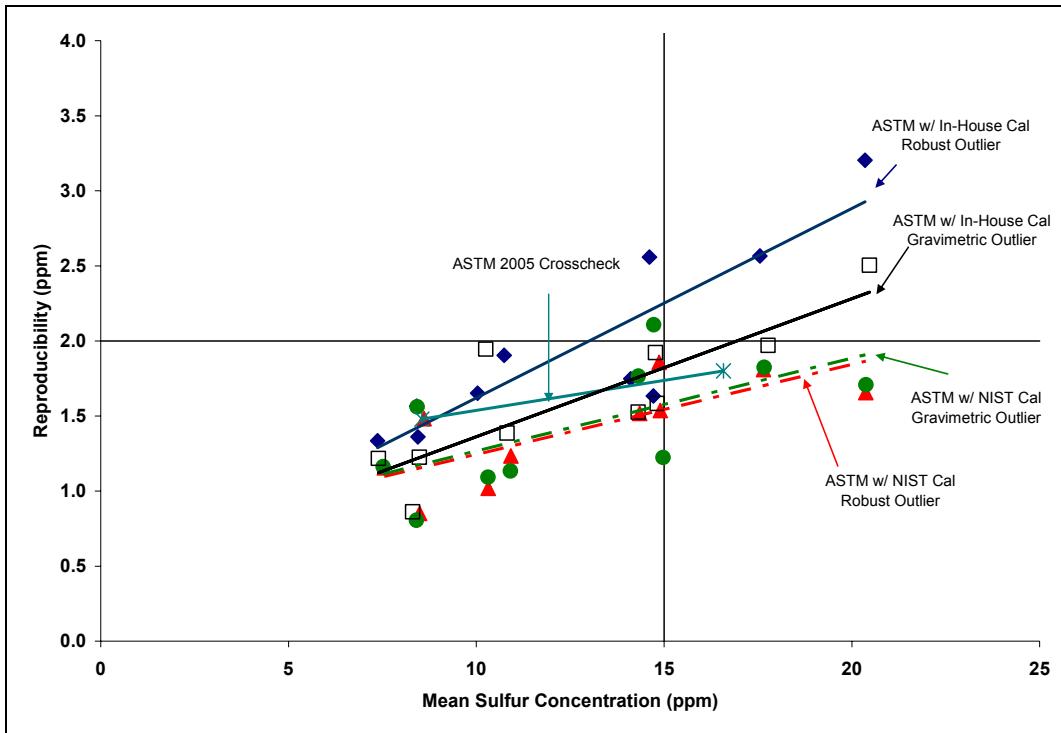

The comparison was achieved by fitting straight-line regression models having the following form:

$$\text{Reproducibility} = \text{Intercept} + (\text{Coefficient}) * (\text{Mean Sulfur}).$$

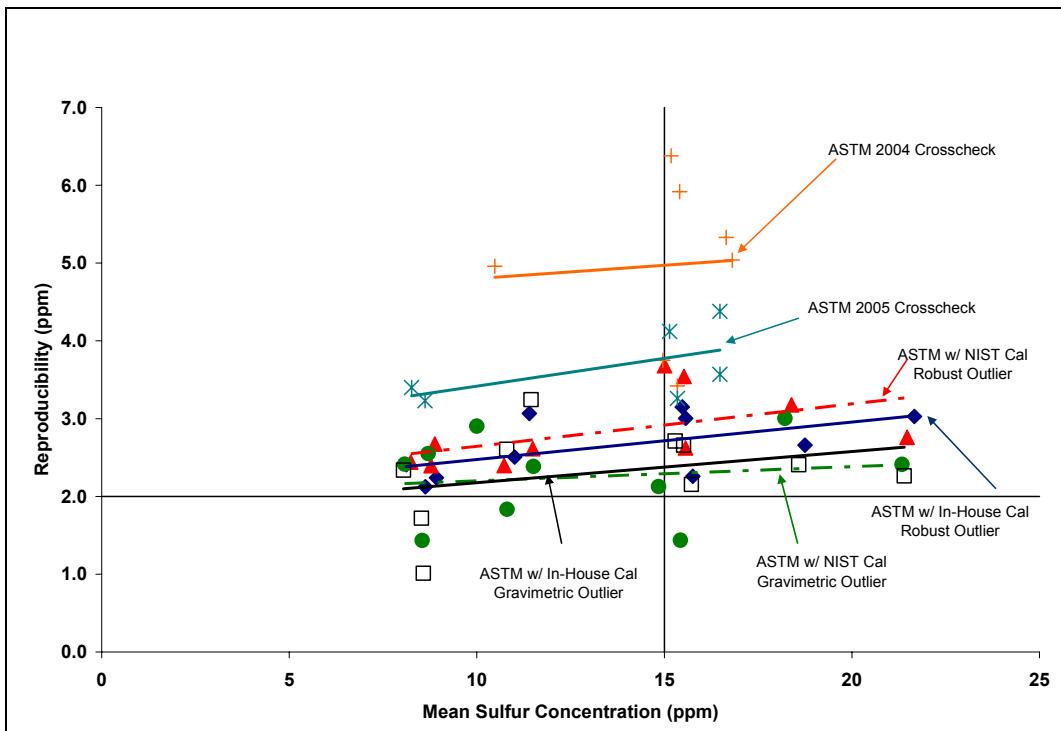

The resulting regression models were then used to predict and compare the R-values when the mean sulfur was set at 15 ppm. The data and fitted regression models are illustrated in the plots in Figures 47-52. Table 9 contains a list of the predicted R-values at a mean sulfur of 15 ppm for both the ASTM CC and the EPA RR categories used in the regression fits.

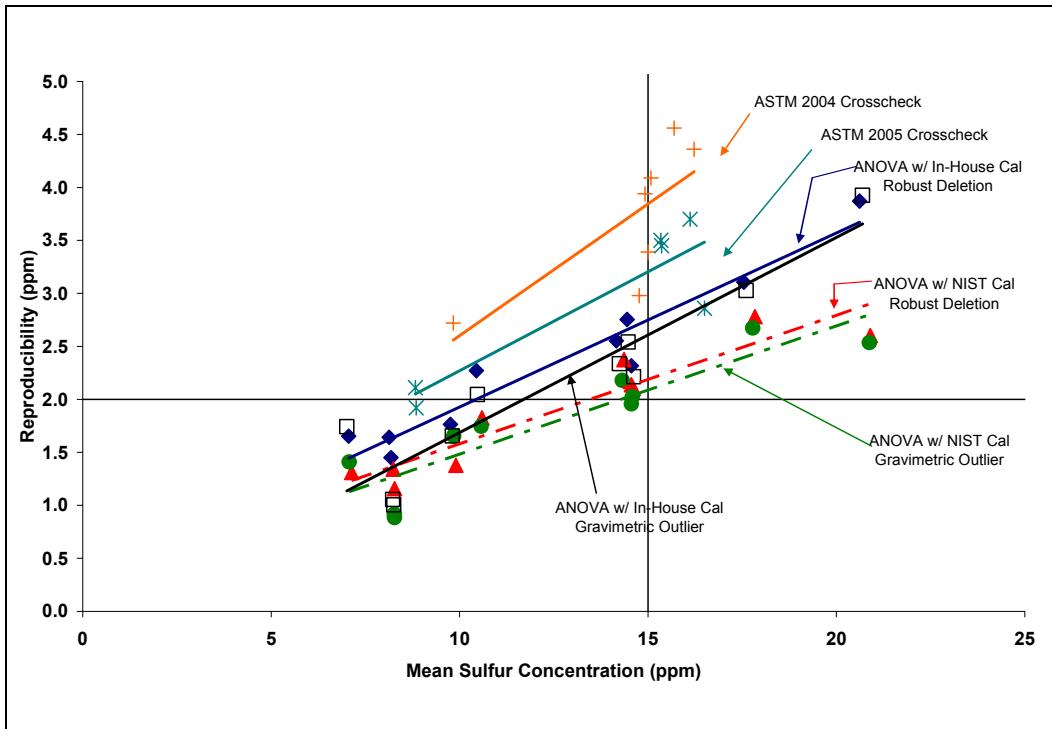

**Figure 47. Plot and Regressions of ASTM Reproducibility vs. Mean Sulfur for D 5453 Data Categorized by ASTM Crosscheck and ASTM EPA Round-Robin Results**

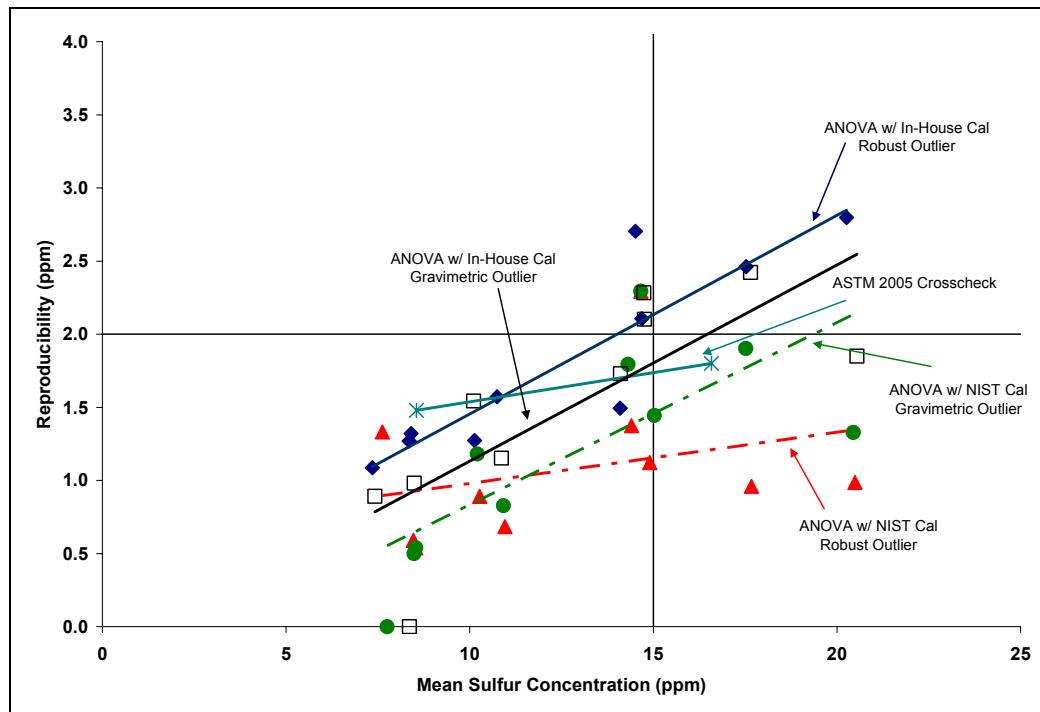

**Figure 48. Plot and Regressions of ASTM Reproducibility vs. Mean Sulfur for D 7039 Data Categorized by ASTM Crosscheck and ASTM EPA Round-Robin Results**

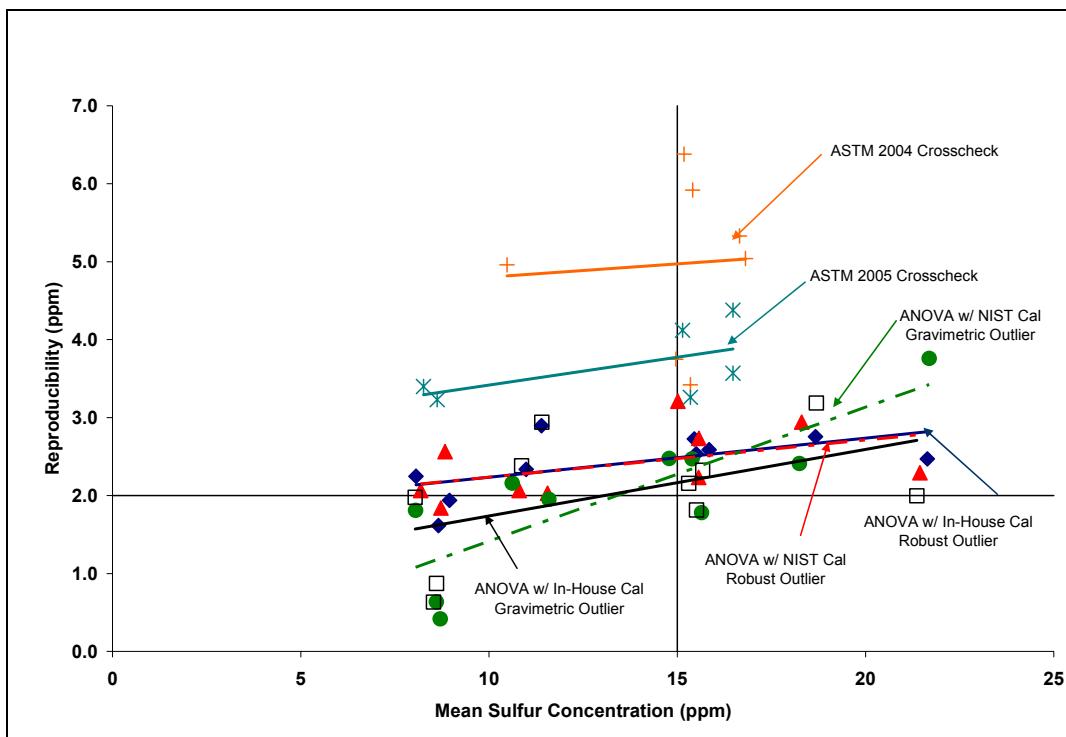

**Figure 49. Plot and Regressions of ASTM Reproducibility vs. Mean Sulfur for D 2622 Data Categorized by ASTM Crosscheck and ASTM EPA Round-Robin Results**

**Figure 50. Plot and Regressions of ASTM Reproducibility vs. Mean Sulfur for D 5453 Data Categorized by ASTM Crosscheck and ANOVA EPA Round-Robin Results**

**Figure 51. Plot and Regressions of ASTM Reproducibility vs. Mean Sulfur for D 7039 Data Categorized by ASTM Crosscheck and ANOVA EPA Round-Robin Results**

**Figure 52. Plot and Regressions of ASTM Reproducibility vs. Mean Sulfur for D 2622 Data Categorized by ASTM Crosscheck and ANOVA EPA Round-Robin Results**

**Table 9. Predicted R-Values at 15 ppm Sulfur for the ASTM CC and EPA RR Data**

Approach	Test Method	ASTM Reproducibility	ANOVA Reproducibility
ASTM 2004 CC	D 2622	4.97	
	D 5453	3.84	
ASTM 2005 CC	D 2622	3.78	
	D 5453	3.20	
	D 7039	1.74	
NIST Calibration Gravimetric Deletion	Composite	1.87	1.96
	D 2622	2.29	2.27
	D 5453	1.71	2.09
	D 7039	1.58	1.46
NIST Calibration Robust Deletion	Composite	2.21	2.15
	D 2622	2.91	2.47
	D 5453	1.93	2.19
	D 7039	1.54	1.15
In-House Calibration Gravimetric Deletion	Composite	2.22	2.23
	D 2622	2.38	2.16
	D 5453	2.09	2.61
	D 7039	1.82	1.80
In-House Calibration Robust Deletion	Composite	2.86	2.64
	D 2622	2.71	2.49
	D 5453	2.68	2.75
	D 7039	2.25	2.13

Based on the results listed in Table 9, the regression equations produced lower predicted R-values (at 15 ppm sulfur) for the EPA RR results relative to the 2004 and 2005 ASTM CC results. The EPA RR predicted values are lower for D 5453 and D 2622, and the predicted values are comparable for D 7039.

The reproducibility data in the table and the previous graphs support several conclusions:

- Limiting the RR participation to labs that have qualified their methods under 40 CFR 80.584 had a favorable impact on lowering reproducibility.
- Using the identical NIST calibration curves across the participating labs reduced curve bias contributions to reproducibility.
- A reduction in predicted R (at 15 ppm sulfur) for the EPA RR data over the predicted R-values obtained using the 2004 and 2005 CC data was apparent in all cases when using the NIST calibration curves. The magnitude of the reduction in predicted R (ASTM R, at 15 ppm) from In-House to NIST under robust deletion was 0.73 ppm on average for D 5453 and D 7039 (excluding D 2622).
- Using gravimetric outlier deletion further improved reproducibility. Use of this method can be analogous to a calibration check standard.
- The newer test methods produced results with lower R (D 5453 and especially D 7039).

- Results show that there is still opportunity for further improvement with respect to reduction in lab-to-lab variability. This is evidenced by
  - the difficulty some labs had in accurately measuring the blind gravimetric calibration check standard.
  - the inability of some labs to qualify their instruments and the wide range in results for those that did qualify.
  - the difficulty some labs had in re-calibrating their instrument using the NIST SRMs.

**C. Statement of Work:**

EPA 2006 Sulfur in Diesel Fuel Round Robin Test Plan  
and Data Analysis

**C. Statement of Work:****BACKGROUND**

The Environmental Protection Agency's (EPA) 2007 Highway Heavy-Duty Diesel Rule requires 80% of the highway diesel fuel sold after June 1, 2006 to contain 15 ppm sulfur or less. This regulation allows for a 2 ppm downstream test tolerance at the point of sale, thus affording a maximum measured sulfur level of 17 ppm. Recent evaluations of the reproducibility of sulfur measurement test methods on a lab-to-lab basis has called the 2 ppm downstream test tolerance into question.

Results of the ASTM 2002 ULSD Round Robin and 2004 ULSD Interlaboratory Cross Check Program (ILCP) have revealed that the lab-to-lab reproducibility of current sulfur test methods is greater than 2 ppm. EPA is concerned that the reproducibility has been biased high in these programs due to a number of factors not limited to the following:

1. Insufficient/inappropriate instrument calibration at low sulfur concentrations.
2. Inaccurate calibration standards.
3. Insufficient quality assurance when testing at low sulfur levels.
4. Lax statistical processing for the elimination of outliers from the reproducibility calculation.

This concern has driven EPA to construct a Round Robin program of its own to make a determination of reproducibility.

**NATURE OF THE WORK ASSIGNMENT**

This work assignment focuses on reviewing EPA's test plan and data processing plan for its 2005 ULSD Round Robin test program. Based on this investigation, a recommendation will be requested

for the statistical determination and treatment of outliers in EPA's 2005 ULSD Round Robin Program taking into consideration the criteria for laboratories to qualify their sulfur test methods via the Performance Based Measurement System (PBMS) as described in 40 CFR 80.580 - 80.585. EPA will also ask that the contractor process the data from the EPA Round Robin program using the method recommended.

## STATEMENT OF WORK

The contractor shall submit a detailed work plan to EPA for approval. The work plan shall include a detailed description of how the tasks described below are to be performed. The work plan shall include suggested alternates for any of the required tasks if they are thought necessary together with justifications for these recommendations. The costs for the work plan shall be broken down by task.

### Materials

The contractor shall use data provided via laboratories participating in the 2005 US EPA ULSD Round Robin. All materials purchased using government funds shall be considered the property of the U.S. Government and shall be returned to EPA after completion of the Work Assignment.

### Task 1

#### **Objective:**

Review EPA's test plan and proposed methods for calculation of reproducibility in it's 2005 ULSD Round Robin test program. Make a determination on which method is better for statistical handling of outliers and comment on the test plan. The goal of the test plan is to provide a procedure to determine a realistic reproducibility value among labs with respect to their ability to measure sulfur in ULSD fuel. The results would be a prediction of what reproducibility can be achieved in the future after all labs are testing ULSD fuel samples on a routine basis pursuant to the provisions in the regulations.

#### **Task Description:**

The EPA 2005 ULSD Round Robin test plan shall be reviewed in its entirety. EPA would like to use the results of this data to determine whether or not its 2 ppm downstream test tolerance for ULSD fuel is adequate for measurement of ULSD fuel or if the test tolerance needs to be adjusted. The goal of the test plan is to determine the lab-to-lab reproducibility of labs that have qualified their sulfur measurement method with EPA as stated in 40 CFR 80.580. The test plan has been designed to minimize variability. Two options for the elimination of outliers is proposed. The first method is identical to the method that ASTM uses to determine reproducibility in its Round Robin and ILCP. This method will used to calculate reproducibility to act as a direct comparison to the ASTM programs. The second method compares the standard deviation of three repeat measurements of a blind SRM with an accuracy requirement of a maximum standard deviation of 0.90 ppm. This is based on a variation of the test method qualification under 40 CFR 80.584. This variation takes into account the lower number of repeat measurements then is required in 40 CFR 80.584, as well as the

gravimetric standard uncertainty. There is concern that the ASTM method does not do an adequate job of excluding outliers whose values significantly vary from the average. EPA requests that the contractor investigate this and report back to EPA on the merits of each method and its recommendation for which method (s) to utilize. The contractor may also recommend alternate techniques for excluding outlier data and should include a detailed summary on the merits of these techniques.

## Task 2

### **Objective:**

Perform statistical analysis of the data submitted by the labs, as stated in the 2005 ULSD Round Robin test plan, using the procedure(s) agreed upon in Task 1. This analysis will include analysis of the data using the ASTM procedure and any others as recommended as an outcome of the Task 1 evaluation.

### **Task Description:**

The contractor shall calculate the mean, standard deviation, repeatability, and reproducibility for each of the five monthly samples using the calculations as stated in the test plan and determined in Task 1. EPA anticipates a minimum of 20 and a maximum of 80 labs participating in this test program. Five samples will be sent out each month and run in triplicate. The attached test plan should be used as guidance for the overall scope of the program. Examples of the ASTM calculations are available in excel format and will be provided by EPA (see attached files: ULSD Computations.xls and ULSD Draft Data Table.xls). The data shall be graphed and organized in a manner that allows ease of interpretation. All equations used in the calculations shall be made known and their variables explained.

### **D. Deliverables:**

The contractor shall provide 3 copies of all reports to EPA (excluding weekly reports).

#### *1. Work Plan and Quality Assurance Project Plan*

The contractor shall submit a detailed work plan to EPA for approval as described above. The work plan shall include a cost estimate for each task described in the statement of work.

#### **2. Weekly Reports**

The contractor shall provide 30-60 minute phone conference reports every week that summarize progress to date.

#### **3. Draft Final Report**

The contractor shall provide a draft report summarizing the results of the work assignment as described in Tasks 1 and 2 above.

#### 4. Final Report

The contractor shall provide a final, citable report for use by EPA. The final report shall incorporate comments from the work assignment regarding the draft final report. The final report shall include all the data submitted from the test labs and data analysis techniques. The material must be in hardcopy form as well as in an electronic format agreed upon in advance. Microsoft Excel, Word, or Adobe portable document files (\*.pdf) are acceptable.

#### 5. Test Data

All test data collected while performing the work detailed in this Statement of Work shall become the property of the EPA. Data shall be submitted electronically in ASCII format or other agreed upon electronic file such as Microsoft Excel.

Deliverables shall be submitted as follows:

Deliverable:	Proposed Completion Date
Task 1:	April 15, 2005
Complete Task 2 Data Analysis:	August 15, 2005
Complete draft report:	August 31, 2005
Complete final report:	15 days after receiving comments from EPA

#### E. Task Completion

The contractor shall provide an opportunity for EPA to receive a short weekly status report via phone conference during the Work Assignment period. The oral report shall indicate the progress achieved in the concluded weeks, technical problems encountered, solutions to those problems (proposed and attempted), and projected activity for the upcoming weeks. This report shall include an estimate of the percentage of the level of effort expended and a percent of task completed to date. The Work Assignment Manager or his/her designated alternate shall participate in these phone conferences.

**DRAFT – Do Not Circulate****TEST PLAN****2005 US EPA ULSD Round Robin****INTRODUCTION**

The US EPA Office of Transportation and Air Quality will be organizing an Ultra Low Sulfur Diesel (ULSD) Round Robin (RR) in the months of June and July 2005. This document describes the requirements laboratories must meet to participate in the RR, as well as the overall test plan.

**REGISTRATION REQUIREMENTS**

Labs that wish to participate in the RR must register with EPA by May 20, 2005. To register, please send your companies name, contact, mailing address, contact phone number, and contact's e-mail address to the following:

Chris Laroo  
US EPA  
Office of Transportation and Air Quality  
Assessment and Standards Divisions  
2000 Traverwood Dr.  
Ann Arbor, MI 48105  
[laroo.chris@epa.gov](mailto:laroo.chris@epa.gov)

All labs will be identified by name with their results thus results will not be held confidential. By registering for this program, you agree to these terms. Registration will be limited to 80 labs.

**LABORATORY REQUIREMENTS**

Only laboratories that have had their sulfur measurement methods qualified by EPA via the Performance based Measurement System (PBMS) as described under 40 CFR 80.580 – 80.585 will be allowed to participate in the RR. Thus this RR is open to all sulfur test methods as qualified under 40 CFR 80.584 and 80.585. While official approval by EPA is not required, the laboratory must have written documentation from EPA stating that the qualification data was acceptable as received. EPA will review each registered lab against its lab qualification database to insure conformity.

**TEST PLAN**

Samples will be sent out for analysis at the beginning June and July. A form will accompany each month's sample set describing how the samples shall be analyzed, results recorded, and where the results are to be sent. A submission deadline for the results will also be given.

**DRAFT – Do Not Circulate****Calibration Method**

Laboratories will be required to generate a four point calibration curve using calibration standards provided each month by EPA. These calibration standards will consist of National Institute of Standards and Technology (NIST) Standard Reference Materials (SRMs). The SRMs that will be used, with their concentration and uncertainty, are as follows:

SRM #	Certified Value	Uncertainty (ppm)
2771*	0.2	±0.2
1616b	8.41	±0.12
2723a	11	±1.1
2770	41.57	±0.39

Please note that at this time the certified value and uncertainty for SRM 2771 is preliminary and should be final by the time the RR begins. SRM 1616b is sulfur in kerosene and it is anticipated that matrix effects due to the difference in the hydrogen to carbon ratio should be minimal.

EPA will ask that each lab calibrate their instrument using these SRMs before beginning analysis of the fuel samples. Three 10 ml ampoules of each SRM will be provided each month.

**Test Materials**

A total of 10 fuel samples (80 ml each) will be sent out over the course of the two month program. Five samples will be sent out with a set of SRMs on the first of each month. All five of the samples sent out each month will be blind. Of the five samples, one may be a gravimetric standard. The target sample sulfur concentrations will be in the range of 4 to 20 ppm.

Laboratories will be asked to make three repeat measurements on each of the fuel samples. Sulfur values shall be reported out to the nearest tenth of a ppm.

**DATA ANALYSIS**

Data shall be submitted directly to Southwest Research Institute as they have been contracted to perform the data analysis. A data sheet will accompany the monthly samples with instructions on how to fill out the sheet as well as where to send it.

Results will be reported on both a composite (all data grouped together regardless of method) and method specific basis (where enough labs have run the specific method for statistical analysis). Data analysis will include calculation of mean, standard deviation, repeatability, and reproducibility.

Outliers will be determined using a two-stage robust procedure and is outlined in the next paragraph. EPA is also considering potential screening for outliers based on the

**DRAFT - Do Not Circulate**

measurement results of the blind gravimetric standard. For this determination, the arithmetic average of the three repeat tests performed on the blind gravimetric sample shall not differ from the accepted standard reference value of the standard by more than 0.90 ppm. The value takes into consideration the 95% two-sided confidence interval for three repeat measurements, as well as real bias and gravimetric standard uncertainty. This will, in effect, hold the laboratories measurement capability in line with that of the PBMS method qualification criteria for accuracy as stated in 40 CFR 80.584. EPA is also asking SwRI to offer suggestions on other means of data calculation and outlier determination.

The means and standard deviations will be computed using a two-stage robust procedure which is designed to limit the influence of unusually large or small results, while eliminating only the most egregious among them. Data will be subjected to the robust computations twice. After the first stage, results which differ from the (first stage) robust mean by more than three times the (first stage) robust standard deviation are noted as outliers and excluded from the second-round robust computation. The robust mean and standard deviation are then recalculated using the second-stage computation (there is no second stage exclusion in this calculation). As the second-stage robust standard deviation is generally smaller than that of the first stage, some non-excluded results may differ from the robust mean by more than three robust standard deviations.

A description of an iterative algorithm for computing robust means and standard deviations is provided in the next section. The process is tedious, but the estimates do have the following property which can easily be verified. If  $n$  results are included in the computation, and if all the results which differ from the robust mean by more than  $1.5\sqrt{(n-1)/n}$  times the robust standard deviation are replaced by the robust mean,  $\pm 1.5\sqrt{(n-1)/n}$  robust standard deviations, as appropriate. The mean of these "trimmed" results will equal the robust mean, and the standard deviation of the trimmed results will be .882 times the robust standard deviation.

**Calculation of Robust Mean and Robust Standard Deviation**

The Robust Mean and Robust Standard Deviation of a collection of  $n$  results are calculated by first finding the median of all test results and then finding each result's absolute deviation from this median. An initial standard deviation for the reported results is determined by dividing the median of the absolute deviations by 0.6745. This value is multiplied by a cutoff value ( $1.5\sqrt{(n-1)/n}$ ) and the result is added and subtracted from the median of the test results to arrive at initial upper and lower limits.

For calculation purposes, test results that fall within these limits are retained, and other results are adjusted to the nearest limit. A robust mean and robust standard deviation are calculated using this new set of values (Robust Mean = average of trimmed results; Robust Standard Deviation = standard deviation of results divided by 0.882). The robust standard deviation is compared to the initial standard deviation estimates determined above. If they are equal then record the values as the robust mean and robust standard

**DRAFT - Do Not Circulate**

deviation. If the standard deviations are not equal, then a loop process begins by utilizing the robust average and standard deviation to calculate a new set of upper and lower limits. This looping process continues until the robust standard deviation stabilizes from one iteration to the next. The resulting values are the Robust Mean and Robust Standard Deviation. The number of digits carried out in the loop process is one digit more than the reporting resolution of the test values.

**Calculating Repeatability (r) and Reproducibility (R)**

The results from all labs are entered into the robust routine. After the first pass, a number of outliers may be identified. Let  $N_R$  be the number of valid results,  $m_R$  is the robust mean,  $s_R$  is the robust standard deviation, and  $M_R$  is the number of labs for which both of the replicate measurements were valid.

For example, ID 2622 data from the October, 2004 ULSD exchange, 50 labs contributed 2 numerical results each. Nine of these 100 results were flagged as outliers on the first pass of the robust routine, so  $N_R = 91$ ,  $m_R = 16.8088$  and  $s_R = 1.8090$ . Of the 50 contributing labs, 4 had both results flagged and one had one result flagged. Thus  $M_R = 50 - 4 - 1 = 45$ .

Next, calculate the difference between results for each lab that contributed valid results. For this calculation the second and third results from each sample will be used. Compute both the positive and negative difference for each lab. Dump these  $2M_R$  differences into the robust routine. The robust mean will be zero, and the number of outliers flagged on the first pass will always be even (if a result is flagged, then its negative will be, too). Let  $N_r$  be the number of differences remaining after outlier selection, and  $M_r = N_r / 2$  the number of labs contributing valid differences. Let  $s_r$  be the robust standard deviation. In our example, 45 pairs of differences, or 90 total, were taken to the robust routine. 6 differences (3 pairs) were flagged as outliers, so  $N_r = 90 - 6 = 84$  and  $M_r = 45 - 3 = 42$ .  $s_r = 0.69256$ .

Next, calculate the repeatability estimate:

$$r = 1.9600 \sqrt{\frac{2M_r - 1}{2M_r}} s_r$$

Then calculate the reproducibility estimate:

$$R = \sqrt{\frac{N_R(N_R - 1)(2.7718s_R)^2 - 2M_Rr^2}{N_R(N_R - 1) - 2M_R}}$$

**DRAFT - Do Not Circulate**

**Reporting of Data**

Data reports may be sent to all of the participating test labs within 30 days of the conclusion of the test program. The reports will also be made available on-line.

## **APPENDIX A2**

**AMENDMENT NO. 1 TO WORK ASSIGNMENT**

**AMENDMENT NO. 2 TO WORK ASSIGNMENT**

## 2005 US EPA ULSD Round Robin Test Plan

### INTRODUCTION

The US EPA Office of Transportation and Air Quality will be organizing an Ultra Low Sulfur Diesel (ULSD) Round Robin (RR) in the months of July and August 2005. This document describes the requirements laboratories must meet to participate in the RR, as well as the overall test plan.

### REGISTRATION REQUIREMENTS

Labs that wish to participate in the RR must have register with EPA by May 27, 2005. Registration is now closed. Laboratories do not have to have their qualification data submitted to register for the program. However, we ask that all registered participants submit their qualification data no later than June 27, 2005. EPA will allow and extension of this date on a case-by-case basis and will make every attempt to insure that each registered lab is able to participate. Please contact Chris Laroo if you have any concerns regarding qualification. His contact information is as follows:

Chris Laroo  
US EPA  
Office of Transportation and Air Quality  
Assessment and Standards Divisions  
2000 Traverwood Dr.  
Ann Arbor, MI 48105  
(734) 214-4937  
[latoo.chris@epa.gov](mailto:latoo.chris@epa.gov)

A list of all participating labs will be published in the final report. All data will be coded and the laboratories identification will be known only to EPA. Therefore, the labs will not be directly linked to their results. Laboratories will be given a numerical code to represent their data. By registering for this program, you agree to these terms. Registration is currently limited to 120 labs.

### LABORATORY REQUIREMENTS

Laboratories that meet the Performance based Measurement System (PBMS) qualification criteria as described under 40 CFR 80.580 – 80.585 will be allowed to participate in the RR. Thus this RR is open to all sulfur test methods as qualified under 40 CFR 80.584 and 80.585. While official approval by EPA is not required, the laboratory must have received notice from EPA stating that the qualification data was acceptable as received. This notice will be sent out via e-mail. EPA will review each registered lab against its lab qualification database to insure conformity.

### TEST PLAN

Samples will be sent out for analysis at the beginning of July and August. A form will accompany each month's sample set describing how the samples shall be analyzed, results recorded, and where the results are to be sent. You will be asked to e-mail your results to an e-mail address at Southwest Research Institute that will be provided. An excel data submission template will be sent out via e-mail to all participants on the day that the samples are shipped. A submission deadline for the results will also be given.

#### Calibration Method

Laboratories will be asked to analyze five blind fuel samples per month using both their instrument's existing "in-house" calibration curve as well as a four point calibration curve that is generated using calibration standards provided each month by EPA.

Laboratories will be asked to provide the following information regarding their "in-house" calibration standards: The number of calibration standards used to generate the calibration curve, the name of the calibration standard source, the Accepted Reference Value (ARV) of each standard, the expanded uncertainty (95% confidence interval for the true value) of the standards, and the matrix with which the standard is composed of (for example, sulfur in diesel fuel is considered a natural matrix). EPA will also ask that the labs provide the same information for any check standard that is used to verify the calibration curve as well as what the lab's test result was for the check standard.

The calibration standards provided by EPA to generate the calibration curve will consist of National Institute of Standards and Technology (NIST) Standard Reference Materials (SRMs). The SRMs that will be used, with their concentration and uncertainty, are as follows:

SRM #	Certified Value	Uncertainty (ppm)
2771	0.2	±0.2
1616b	8.41	±0.12
2723a	11	±1.1
2770	41.57	±0.39

Please note that at this time the certified value and uncertainty for SRM 2771 is preliminary and should be final by the time the RR begins. SRM 1616b is sulfur in kerosene and it is anticipated that matrix effects due to the difference in the hydrogen to carbon ratio should be minimal.

All calibration standard bottles will be clearly marked with NIST labeling. EPA will ask that each lab calibrate their instrument using these SRMs after analyzing the blind fuel samples with the existing instrument calibration. Thus the instrument will be set up with an approximate 0 to 42 ppm range. The labs will then be instructed to reanalyze the fuel samples with this new calibration.

The purpose of the analysis using multiple calibration curves is to provide a real world analysis of the blind fuel samples using methods that are qualified to EPA's Performance Based Measurement System as well as determining the effect of the use of highly accurate universal calibration standards on lab-to-lab variability.

Three 10 ml ampoules of SRM 2723a and 2770 will be provided each month. SRMs 2771 and 1616h are packaged by NIST in 100 ml amberlite bottles. For these SRMs, one 100 ml bottle of each will be sent out during the first month of the program. Laboratories will be instructed to save these SRMs after use for use in the second month of the program where we will ask them to generate another calibration curve before the second measurement of the fuel samples. Please note that use of this calibration curve, which in most cases will be different from the calibration curve used to qualify your lab's sulfur measurement method, does not require you to requalify your method with the new curve. It is anticipated that laboratories will use their standard in-house procedures to validate the calibration curve.

If your laboratory has registered and qualified more than one sulfur measurement method, you will still only receive the same quantity of SRMs as a normal lab. When determining the volume of SRMs that were to be sent out to a lab for this program for calibration, excess volume was built in. It is anticipate that this excess will be sufficient for labs to calibrate more than one method per month if needed.

#### Test Materials

A total of 10 fuel samples (80 ml each) will be sent out over the course of the two month program. Five samples will be sent out with a set of SRMs on the first of each month. All five of the samples sent out each month will be blind. Of the five samples, one may be a gravimetric standard. The target sample sulfur concentrations will be in the range of 7 to 17 ppm. All blind fuel sample bottles will be clearly labeled for identification (ex. EPA Low Sulfur Diesel Round Robin July Sample #1).

Laboratories will be asked to make three repeat measurements on each of the fuel samples for each of the calibration curves. The labs should run these three samples back-to-back-to-back using the same operator and same lab equipment. The instrument shall not be recalibrated using the NIST SRMs until all of the fuel samples have been analyzed on the initial "in-house" calibration curve. Following the recalibration, the fuel samples are to be analyzed in triplicate again. Sulfur values shall be reported out to the nearest tenth of a ppm.

For methods like D 5453 that require that a sample be analyzed three times and then average to obtain one data point, operators should analyze the sample nine times as required and then report the three average values taken from the average of each grouping of three measurements.

If your laboratory has registered and qualified more than one sulfur measurement method, you will still only receive the same quantity of blind fuel samples as a normal lab. It is anticipate that the volume supplied should be sufficient for analysis by laboratories running more than one sulfur measurement method.

## DATA ANALYSIS

### Data Collection

Data shall be submitted directly to Southwest Research Institute via e-mail as they have been contracted to perform the data analysis. A data sheet will be e-mailed to all participants on the day that the monthly samples are shipped. Instructions on how to fill out the sheet as well as where to send it will be included in the e-mail as well as shipped with the samples.

### Descriptive Statistics

Results will be reported on both a composite (all data grouped together regardless of method) and test method specific basis (where enough labs have run the specific method for statistical analysis) for the measurement results generated from analysis using both the lab's "in-house" calibration curve as well as the calibration curve generated using the NIST SRMs. Descriptive statistics (sample size, mean and standard deviation) from all sulfur data received from the participating labs will be computed before and after any outliers are identified on both the composite and test method specific basis. This will be done for each of the fuel samples using the calculations as stated in the test plan. For method specific groupings, at least 6 labs with valid sulfur measurements from each test method for all fuels (i.e., after outlier checks have been performed) will be required to make a final statement about the reproducibility.<sup>1</sup> Data analysis for the composite and method specific groupings will also include repeatability and reproducibility. An attempt will be made to fit a curve to the reproducibility results on both a composite and test method specific basis. The purpose will be to provide a means to determine reproducibility based on fuel sulfur level. While the range of sulfur levels in the blind fuel samples is broad enough support the generation of these curve fits, the ability to generate the fits will be dependant on the variability of the data and the decision to go forth will be made during the data analysis.

### Outliers

Outliers will be determined using two different methods. In the first method, outliers will be determined using a two-stage robust procedure, identical to that used in the 2004 ASTM ILCP. Since RPA is requiring that the blind fuel samples be measured in triplicate, a random selection of two of the three test results for each fuel sample will be made for computing the repeatability and reproducibility. In the case where two of the three test results are valid, no selection is necessary. In the case where only one test result is valid, the lab would be eliminated for that fuel in that particular month.

EPA is also considering potential screening for outliers based on the measurement results of the blind gravimetric standard. For this determination, the arithmetic average of the three repeat tests performed on the blind gravimetric sample shall not differ from the accepted standard reference value (ARV) of the standard by more than 0.90 ppm. The value takes into consideration the 95% two-sided confidence interval for three repeat measurements, as well as real bias and gravimetric standard uncertainty. This will, in effect, hold the laboratories measurement capability in line with that of the PBMS method qualification criteria for accuracy as stated in 40 CFR 80.584. If a laboratory's arithmetic average of the three repeat tests on the gravimetric sample differs from the ARV of the standard by more than 0.90 ppm, all of the laboratory's data for all fuel measurements for that month will be thrown out. If a laboratory's ARV is 0.90 ppm or less, all of the laboratory's data will be processed using the two-stage robust procedure as discussed below.

The outlier detection procedures will be applied to sulfur results obtained by similar test methods and as a composite of all test methods. The means and standard deviations will be computed using a two-stage robust procedure which is designed to limit the influence of unusually large or small results, while eliminating only the most egregious among them. Data will be subjected to the robust computations twice. After the first stage, results which differ from the (first stage) robust mean by more than three times the (first stage) robust standard deviation are noted as outliers and excluded from the second-round robust computation. If any individual sulfur measurement falls outside this interval then it is identified as an outlier. After this identification step, EPA will be provided a list of the outliers so that they can review them and possibly consult with the individual labs about related transcription errors, data entry errors, etc. The robust mean and standard deviation will then be recalculated using the second-stage computation (there is no second stage exclusion in this calculation). As the second-stage robust standard deviation is generally smaller than that of the first stage, some non-excluded results may differ from the robust mean by more than three robust standard deviations.

After the results are checked for outliers on a per test method basis, the resulting valid measurements from all the test methods will be merged together and the descriptive statistics as described above will be recomputed.

A description of an iterative algorithm for computing robust means and standard deviations is provided in the next section. If  $n$  results are included in the computation, and if all the results which differ from the robust mean by more than  $1.5\sqrt{(n-1)/n}$  times the robust standard deviation are replaced by the robust mean,  $\pm 1.5\sqrt{(n-1)/n}$  robust standard deviations, as appropriate. The mean of these "trimmed" results will equal the robust mean, and the standard deviation of the trimmed results will be .882 times the robust standard deviation.

#### Calculation of Robust Mean and Robust Standard Deviation

The Robust Mean and Robust Standard Deviation of a collection of  $n$  results are calculated by first finding the median of all test results and then finding each result's absolute

deviation from this median. An initial standard deviation for the reported results is determined by dividing the median of the absolute deviations by 0.6745. This value is multiplied by a cutoff value ( $1.5\sqrt{(n-1)/n}$ ) and the result is added and subtracted from the median of the test results to arrive at initial upper and lower limits.

For calculation purposes, test results that fall within these limits are retained, and other results are adjusted to the nearest limit. A robust mean and robust standard deviation are calculated using this new set of values (Robust Mean = average of trimmed results; Robust Standard Deviation = standard deviation of results divided by 0.882). The robust standard deviation is compared to the initial standard deviation estimates determined above. If they are equal then record the values as the robust mean and robust standard deviation. If the standard deviations are not equal, then a loop process begins by utilizing the robust average and standard deviation to calculate a new set of upper and lower limits. This looping process continues until the robust standard deviation stabilizes from one iteration to the next. The resulting values are the Robust Mean and Robust Standard Deviation. The number of digits carried out in the loop process is one digit more than the reporting resolution of the test values.

#### Calculating Repeatability (r) and Reproducibility (R)

The results from all labs are entered into the robust routine. After the first pass, a number of outliers may be identified. Let  $N_R$  be the number of valid results,  $m_R$  is the robust mean,  $s_R$  is the robust standard deviation, and  $M_R$  is the number of labs for which both of the replicate measurements were valid.

For example, D 2622 data from the October, 2004 ULSD exchange, 50 labs contributed 2 numerical results each. Nine of these 100 results were flagged as outliers on the first pass of the robust routine, so  $N_R = 91$ ,  $m_R = 16.8088$  and  $s_R = 1.8090$ . Of the 50 contributing labs, 4 had both results flagged and one had one result flagged. Thus  $M_R = 50 - 4 - 1 = 45$ .

Next, calculate the differences between results for each lab that contributed valid results. For this calculation the second and third results from each sample will be used. Compute both the positive and negative difference for each lab. Dump these  $2M_R$  differences into the robust routine. The robust mean will be zero, and the number of outliers flagged on the first pass will always be even (if a result is flagged, then its negative will be, too). Let  $N_r$  be the number of differences remaining after outlier selection, and  $M_r = N_r / 2$  the number of labs contributing valid differences. Let  $s_r$  be the robust standard deviation. In our example, 45 pairs of differences, or 90 total, were taken to the robust routine. 6 differences (3 pairs) were flagged as outliers, so  $N_r = 90 - 6 = 84$  and  $M_r = 45 - 3 = 42$ ,  $s_r = 0.69256$ .

Next, calculate the repeatability estimate:

$$r = 1.9600 \sqrt{\frac{2M_r - 1}{2M_r}} s_r$$

Then calculate the reproducibility estimate:<sup>2</sup>

$$R = \sqrt{\frac{N_R(N_R - 1)(2.7718 s_R)^2 - 2M_R r^2}{N_R(N_R - 1) - 2M_R}}$$

#### Alternative Method for Calculation of Repeatability and Reproducibility

As an alternative to the ILCP computations, an analysis of variance (ANOVA) method will be used to compute repeatability and reproducibility for data where outliers were determined using the two-stage robust procedure only. In this situation, all labs with two or three valid sulfur tests per fuel per month would be included. Labs with a single valid sulfur test result per month per fuel would not be included in the computation of repeatability and reproducibility.

#### Total Number of Data Sets

From the different calculation methods for determination of outliers, repeatability, and reproducibility as described above, the following data sets will be generated for comparison purposes from the results of the blind fuel sample analysis for both the "in-house" and NIST SRM calibration curves:

1. Determination of outliers, repeatability, and reproducibility using the two-stage robust test procedure for sulfur measurement methods on an individual basis.
2. Determination of outliers, repeatability, and reproducibility using the two-stage robust test procedure for sulfur measurement methods on a composite basis.
3. Screening of outlier labs based on the measurement results of the blind gravimetric standard. Remaining data from laboratories' whose data is not thrown out will then be subjected to further outlier, repeatability, and reproducibility determination using the two-stage robust test procedure for sulfur measurement methods on an individual basis.
4. Screening of outlier labs based on the measurement results of the blind gravimetric standard. Remaining data from laboratories' whose data is not thrown out will then be subjected to further outlier, repeatability, and reproducibility determination using the two-stage robust test procedure for sulfur measurement methods on a composite basis.
5. Determination of outliers using the two-stage robust test procedure. Determination of repeatability and reproducibility using the ANOVA method for sulfur measurement methods on an individual basis.

6. Determination of outliers using the two-stage robust test procedure. Determination of repeatability and reproducibility using the ANOVA method for sulfur measurement methods on a composite basis.
7. If deemed necessary, processing of the data resulting from the blind gravimetric screening process for outliers will be performed using the two-stage robust test procedure and ANOVA method as described in points 5 and 6.

#### Reporting of Data

Data reports may be sent to all of the participating test labs within 45 days of the conclusion of the test program. The reports will also be made available on-line. A meeting may be scheduled where SwRI will present the data results.

Amendment 2, Work Assignment 0-2  
EPA Contract EP-C-05-018

This amendment requires that 2 changes be made to the content of the round robin final report:

The contractor's final report shall provide 80 additional tables, which are needed to show method-specific test results for robust outlier determination. Currently only composite results are shown. The plots shall show the results for the 10 fuels using 4 methods per fuel and 2 calibration curves per method. This will allow the participating labs to see how they performed on a method-specific basis.

In addition, EPA is requesting changes to the plots in Appendix D to require relabeling of some of the data points. The changes to the plots require adding the test method used to the labeling for all of the ARB and EPA data points. These are the only changes that need to be made to the plots, and this will allow participating laboratories to see how EPA and ARB performed with which test method.

**APPENDIX B**

**LAB DATA AND DATA DELETIONS**

## Appendix B. Lab Data and Data Deletions

### Description of Table Headings

Each table in Appendix B is comprised of all available lab data for the composite test methods by fuel and calibration type. Data are sorted by lab code. Included in the columns of each table is the following information:

1. Calibration – Calibration type (In-House or NIST)
2. Test Method – D2622, D5453, D3120, D7039 and EDXRF.
3. Run Date – The date each sample was run.
4. Sample # - The fuel sample number for each month.
5. Lab Code
6. Original Lab Data Robust Outlier Deletion in Shaded Box, Measure #1, Measure #2, Measure #3 – All three repeat measurements submitted by each lab. Any measurement identified by the robust outlier deletion method is shaded.
7. Density
8. After Robust Outlier Deletion Random Selection of 2 Obs – If no measurements are deleted due to the robust outlier deletion method, one measurement was randomly deleted and the remaining two observations are listed.
9. After Gravimetric Deletion Random Selection of 2 Obs – If a lab has not been deleted due to the gravimetric outlier method, one measurement was randomly deleted and the remaining two measurements are listed. Labs deleted are identified with shaded boxes.

There are four analyses performed with two different deletion methods and two different analysis methods. The data used in each of these four analyses can be found in the tables in Appendix B. These data sets are as follows:

#### 1. Robust Outlier Method and ASTM Analysis

Column #1 and #2 under “After Robust Outlier Deletion Random Selection of 2 Obs”.

#### 2. Robust Outlier Method and ANOVA Analysis

Measure #1, Measure #2, Measure #3 under “Original Lab Data Robust Outlier Deletion in Shaded Box”. Only use the data in the unshaded boxes.

#### 3. Gravimetric Outlier Method and ASTM Analysis

Column #1 and Column #2 under “After Gravimetric Deletion Random Selection of 2 Obs”. Note that deleted labs are shaded and their observations are deleted.

#### 4. Gravimetric Outlier Method and ANOVA Analysis

Measure #1, Measure #2, Measure #3 under “Original Lab Data Robust Outlier Deletion in Shaded Box”. Use all the data (shaded and unshaded) in these three columns except those where the labs were deleted by the gravimetric outlier method (if boxes are shaded under “After Gravimetric Deletion” columns).

**Table B.1. July Fuel #1 Lab Data and Deletions Based on Composite Test Methods for In-House Calibration**

Calibration	Test Method	Run Date	July Sample #	Lab Code	Original Lab Data Robust Outlier Deletion in Shaded Box				Density	After Robust Outlier Deletion Random Selection of 2 Obs		After Gravimetric Deletion Random Selection of 2 Obs	
					Measure #1	Measure #2	Measure #3	#1		#1	#2	#1	#2

## **APPENDIX G**

### **Robust Mean, Robust Standard Deviation, Reproducibility and Repeatability**

**Table G.1. Mean\*, Standard Deviation\*, Reproducibility and Repeatability for July Fuels for Test Method D5453**

In-House Calibration				
	Robust Deletion		Gravimetric Deletion	
	ANOVA	ASTM	ANOVA	ASTM
Fuel 1				
Valid Results	285	191	225	143
Mean	7.06	7.08	7.01	7.14
Std Dev	0.62	0.59	0.65	0.48
Reproducibility	1.65	1.63	1.74	1.33
Repeatability	0.47	0.41	0.50	0.31
Fuel 2				
Valid Results	289	194	225	144
Mean	10.44	10.48	10.47	10.57
Std Dev	0.86	0.83	0.77	0.58
Reproducibility	2.27	2.31	2.05	1.61
Repeatability	0.73	0.38	0.63	0.36
Fuel 3				
Valid Results	285	190	225	148
Mean	20.61	20.66	20.69	20.84
Std Dev	1.42	1.38	1.43	1.10
Reproducibility	3.87	3.82	3.93	3.05
Repeatability	0.77	0.58	0.74	0.58

NIST Calibration				
	Robust Deletion		Gravimetric Deletion	
	ANOVA	ASTM	ANOVA	ASTM
Fuel 1				
Valid Results	273	179	249	158
Mean	7.14	7.15	7.07	7.15
Std Dev	0.51	0.44	0.54	0.34
Reproducibility	1.31	1.22	1.41	0.95
Repeatability	0.55	0.37	0.50	0.40
Fuel 2				
Valid Results	275	178	249	160
Mean	10.59	10.59	10.57	10.62
Std Dev	0.70	0.56	0.69	0.50
Reproducibility	1.82	1.56	1.75	1.38
Repeatability	0.67	0.37	0.78	0.41
Fuel 3				
Valid Results	273	178	249	162
Mean	20.90	20.87	20.88	20.86
Std Dev	1.00	0.88	0.97	0.81
Reproducibility	2.60	2.46	2.54	2.24
Repeatability	0.99	0.58	0.90	0.52

\*For ANOVA analysis, mean and standard deviation are unadjusted estimates.

\*For ASTM analysis, mean and standard deviation are robust estimates.

In-House Calibration				
	Robust Deletion		Gravimetric Deletion	
	ANOVA	ASTM	ANOVA	ASTM
<b>Fuel 4</b>				
Valid Results	286	190	225	150
Mean	8.13	8.12	8.23	8.22
Std Dev	0.62	0.59	0.43	0.45
Reproducibility	1.64	1.63	1.06	1.26
Repeatability	0.55	0.45	0.57	0.46
<b>Fuel 5</b>				
Valid Results	284	190	225	146
