**Re: GE-Pittsfield/Housatonic River Site
On-Plant Consolidation Areas (GECD200)
Response to April 27, 2000 EPA Comments**

Dear Mr. Olson:

In June 1999, the General Electric Company (GE) prepared a document entitled *Detailed Work Plan for On-Plant Consolidation Areas, Pittsfield, Massachusetts* (Detailed Work Plan). Subsequently, in a letter dated July 6, 1999, the United States Environmental Protection Agency (EPA) provided conditional approval of the Detailed Work Plan (subject to certain modifications), and required that GE prepare an addendum to the Detailed Work Plan to address certain EPA comments contained in the July 6, 1999 letter. In response, on August 12, 1999 GE submitted a document entitled *Addendum to June 1999 Detailed Work Plan for On-Plant Consolidation Areas* (Addendum). EPA's comments regarding the Addendum were provided to GE in an attachment to a letter dated April 27, 2000.

Following receipt of EPA's comments to the Addendum, a meeting among representatives of EPA, the Massachusetts Department of Environmental Protection (MDEP), and GE was conducted on May 3, 2000, in Pittsfield, Massachusetts. At that meeting, EPA clarified and modified a number of its comments attached to its April 27, 2000 letter. A follow-up teleconference among the parties was then held on May 30, 2000 to discuss certain technical issues.

Based on these discussions, GE has prepared responses to address the comments contained in the attachment to EPA's April 27, 2000 letter, as clarified and/or modified by EPA. Those responses are provided in Appendix A to this letter. That Appendix addresses in sequence each of the topics discussed in EPA's April 27, 2000 comments. For convenience, for each topic, the Appendix first repeats EPA's comments from its July 6, 1999 and April 27, 2000 letters. It then provides GE's response to each comment. Where EPA has clarified and/or modified a comment during the course of oral discussions, that clarification and/or modification is noted under GE's response. In addition, several attachments to Appendix A are provided to present additional information to supplement GE's responses.

We trust that these responses are sufficient to address EPA's comments. If you have any further questions, please call me or John Novotny.

Sincerely,

Andrew T. Silfer, P.E.
GE Project Coordinator

APPENDIX A

General Electric Company's Responses to EPA's April 27, 2000 Comments on August 1999 Addendum to Detailed Work Plan for On-Plant Consolidation Areas

The Appendix provides the responses of the General Electric Company (GE) to the comments of the U.S. Environmental Protection Agency (EPA), sent to GE by letter of April 27, 2000, regarding GE's August 12, 1999 Addendum to its June 1999 Detailed Work Plan for On-Plant Consolidation Areas. For each topic addressed in those comments, this Appendix first repeats, in italics, EPA's comments from its prior letter of July 6, 1999 (providing conditional approval of the Detailed Work Plan, subject to certain modifications) and its comments of April 27, 2000. It then presents GE's response to each EPA comment. These responses take into account subsequent discussions of the issues among GE, EPA and the Massachusetts Department of Environmental Protection (MDEP) at a meeting on May 3, 2000 and a follow-up teleconference on May 30, 2000. In addition, several attachments are provided to present additional information to supplement GE's responses.

1. Surface Water Runoff Management

EPA's July 6, 1999 Comment 3 on Detailed Work Plan:

Revise to include a section in the Detailed Work Plan text and figures which discusses how surface water runoff will be managed. Discuss the interim and final drainage patterns/retention basins as appropriate.

EPA's April 27, 2000 Comment on August 12 Addendum:

BB&L states that retention basins will be constructed to attenuate and control peak runoff to "the extent practicable" to accommodate runoff resulting from a 25-year/24-hour storm event. Of the three basins described in the BB&L concept for stormwater management, only one (the basin located immediately south of the Building 71 Consolidation Area) is depicted on the drawings presented to date. It is assumed that calculations pertaining to the sizing of this basin, as well as routing of the 25-year design storm through its outlet structure, have been completed.

To date, the Agencies have not obtained for review any stormwater management calculations related to the retention basin(s), relocated storm sewer, swale sizing, etc. GE has indicated that the referenced 1990 HMM Associates report, which concludes that the existing capacity of hydraulic structures (presumably the 30-inch culvert under Merrill Road and the 36-inch culvert in the same vicinity), is insufficient to even accommodate a 10-year storm. BB&L states that as a result of this inadequacy, some modifications may be necessary to the design of the retention basins.

One question regarding the 1990 HMM Associates report is whether it offered any specific recommendations for the upgrading the existing culverts or hydraulic structures to accommodate storms of greater magnitudes.

GE shall provide the Agencies with the design drawings for the surface water runoff structures stormwater management calculations and with a copy of the 1990 HMM report for our review prior to initiating construction of the above-mentioned structures. Without the described stormwater management calculations or information from the referenced 1990 report, the Agencies cannot conduct a meaningful review or offer specific comments or recommendations regarding the suitability or adequacy of the system or features proposed. Upon the Agencies' receipt and review of the design drawings and the 1990 report we will offer our comments regarding stormwater runoff management.

GE Response:

As a general response to the EPA comments regarding this topic, it is important to recognize GE's overall approach concerning near-term and future design and construction activities for the On-Plant Consolidation Areas (OPCAs). First, conceptual design activities for the Building 71 and Hill 78 OPCAs -- including stormwater management systems and related structures -- have already been conducted to provide an overall understanding of long-term, post-closure OPCA conditions. This conceptual design has been previously summarized in the Detailed Work Plan and/or subsequent Addendum to the work plan. Second, to optimize future OPCA-related design, construction, operation, and closure activities, GE intends to develop the OPCAs (within the context of the conceptual design) in a sequential manner, so that specific portions of the OPCAs are only developed as needed.

Consistent with the approach summarized above, GE has to date performed detailed technical design related to only a portion of the Hill 78 and Building 71 OPCAs (i.e., those areas that were anticipated to be needed to address near-future consolidation activities). Related to surface water runoff management, the Detailed Work Plan provided technical drawings for the stormwater basin located immediately south of the Building 71 OPCA (referred to as the 1999 stormwater basin). That basin and its outlet structure have been designed to manage the 25-year, 24-hour storm event. Under the final OPCA configuration, the 1999 stormwater basin will likely manage stormwater runoff from a significant portion of the southern face of the Hill 78 OPCA and the majority of the Building 71 OPCA. The engineering design calculations provided in Attachment 1 delineate the anticipated watershed for the 1999 stormwater basin and outline the methodology employed in its design. The stormwater routing procedure contained in the engineering design calculations results in a 15% reduction in the post-development peak stormwater runoff rate from the 1999 stormwater basin watershed as compared to pre-development conditions during the 25-year, 24-hour design storm. Similar calculations and design drawings for future stormwater basins and control structures will be forwarded for EPA review as the OPCAs are expanded and the designs are completed.

A report entitled *Revised Drainage Analysis Altresco Cogeneration* (HMM Associates, Inc. [HMM], April 1990) compares pre- and post development stormwater runoff conditions for the Altresco Cogeneration (i.e., Pittsfield Generating Company, LLP) project, which is located immediately south of the OPCAs on a leased portion of GE's property. As part of the drainage analysis, HMM estimates the stormwater runoff from the approximately 130-acre watershed that is serviced by the 30-inch diameter culvert at Merrill Road. HMM's analysis indicates that the culvert does not have sufficient capacity to handle the peak stormwater runoff from this watershed during the 10-year, 24-hour and larger storm events. The report does not provide recommendations for upgrading the existing culvert. However, as noted above, the existing and future OPCA stormwater

basins will attenuate future peak discharges such that runoff from the OPCAs will not likely result in increased flooding potential at the Merrill Road culvert (relative to the impacts predicted in the HMM report). It should also be noted that the discharge point in question at the Merrill Road crossing is currently under construction by the Massachusetts Highway Department and will be modified. As requested, two copies of the HMM report were provided to EPA at the May 3, 2000 meeting.

2. Building 71 OPCA Subgrade Preparation

EPA's July 6, 1999 Comment 10 on Detailed Work Plan:

Page 5-11, Section 5.12: Reevaluate the diameter of deleterious material allowable in the consolidation area. Typically, the geotextile vendor has size requirements that should also be adhered to. The puncture requirements shall be evaluated using GRI test methods.

EPA's April 27, 2000 Comment on August 12 Addendum:

Typically no deleterious material is permitted within 6 inches of any geosynthetic component. The procedure suggested by BB&L for preparing the subgrade is theoretically correct but implementing such a procedure may prove difficult. BB&L previously stated that they would remove all deleterious material from the subgrade soil; however, this is impractical. If a layer of clean fill is not to be placed on the sideslopes, a heavy (e.g., 16 oz/yd² or greater) nonwoven needlepunched geotextile shall be used as a cushioning layer between the prepared subgrade and the geomembrane. The cushioning geotextile shall be selected conservatively, assuming a piece of angular glass protruding from the subgrade surface.

With respect to the Consolidation Area floor, BBL shall define the term "clean soil" to be used directly beneath the geomembrane. The particle size distribution must be specified and a puncture calculation performed to determine if there is any potential to damage the geomembrane. GRI Report #13, "A Design Methodology for the Puncture Protection of Geomembranes" describes a method to evaluate puncture potential of geomembranes.

GE Response:

Subgrade preparation activities for the Building 71 OPCA can be divided into two components -- the floor and new perimeter berms (constructed of clean soils from an off-site location), and the existing perimeter embankments. For the portion of Building 71 OPCA constructed in 1999, the new perimeter berms are generally located on the southern and western sides of the OPCA, while the existing perimeter embankments are located on the northern and eastern sides of the OPCA. Activities that were performed to prepare the liner system subgrade in each of the areas are discussed below.

Consolidation Area Floor and New Perimeter Berms

Following removal of existing vegetation and other debris and surface grading, the OPCA area floor and perimeter berms were constructed of clean, imported, well graded sand. The compaction curves and particle size distributions for the sand used at these areas are provided in Attachment 2. As can

be seen from the particle distribution curves, there are no particles greater than two inches in diameter, and over 90% of the particles are smaller than 1/4-inch. The Unified Soil Classification System (USCS) classification for this material is SC, SM, or SC-SM (i.e., silty or clayey sands), making it suitable subgrade soil for this application.

Following placement of the sand layer, any deleterious materials (e.g., large stones, sticks, roots, etc.) were removed. The surface was then compacted using a steel, two drum roller until a smooth, flat surface free of any objects that could potentially puncture the geomembrane was formed. Indentations caused by the edges of the roller were hand-raked to prevent bridging of the overlying geomembrane layer that would contact this prepared surface. For additional protection and cushioning of the geomembrane, the perimeter berms were covered with 12 ounce per square yard (oz/yd²) non-woven geotextile, as discussed below (refer to Attachment 2 for construction information submitted by the contractor for the non-woven geotextile).

Existing Perimeter Embankments

The northern and eastern sides of the OPCA base layer were constructed using the existing embankments. Since the embankments were heavily vegetated, several activities were performed to prepare the subgrade (e.g., clearing and grubbing). Following grubbing activities, the entire area was inspected for any remaining deleterious materials (e.g., large stones, sticks, roots, etc.), and any such materials found were removed. It was then determined that the existing embankment soil materials were suitable for use as the subgrade layer, so the surface was compacted using a steel, two drum roller until a smooth, flat surface free of any objects that could potentially puncture the geomembrane was formed. Indentations in the native sand caused by the edges of the roller were hand-raked to prevent any bridging of the geomembrane. The embankments were then covered with 12 oz/yd² non-woven geotextile prior to geomembrane installation (refer to Attachment 2 for construction information submitted by the contractor for the non-woven geotextile).

Given the particle distribution of the subgrade material, the installation of geotextile on the berms and embankments, the methodology used to prepare the subgrade surfaces, and related puncture calculations (discussed below), the potential for puncture of the geomembrane has been minimized. It should also be noted that EPA representatives were present to oversee subgrade preparation activities and geomembrane deployment, and no issues were identified.

3. Puncture Calculations

EPA's July 6, 1999 Comment 16 on Detailed Work Plan:

Section 6-8: The proposal to allow materials greater than 6-inches in the first lift seems excessive. Puncture calculations shall be provided that substantiate the appropriate particulate size which will not cause damage to the geosynthetic material. Use the GRI method to evaluate.

EPA's April 27, 2000 Comment on GE's August 12 Response:

The geotextile puncture calculations presented use a procedure outlined in the textbook "Designing with Geosynthetics" by R.M. Koerner. Although not a GRI method, the procedure is acceptable.

It is recommended that the puncture potential of the geomembrane also be evaluated. The contribution of any geotextiles in direct contact with the geomembrane shall be included.

GE Response:

An evaluation regarding the potential for puncture of the geomembrane by the overlying soils is not necessary. There are no areas within the OPCA where consolidation soils will be in direct contact with the geomembrane since a geosynthetic drainage composite (GDC) constructed of a geonet and two layers of geotextile will separate the geomembrane from the overlying soils. The calculations previously provided in the Addendum indicate that a single geotextile layer is sufficient to protect the geomembrane from puncture by overlying objects as large as 15 inches. Given that no materials greater than 6 inches will be placed in the first two-foot-thick layer of consolidation materials, it is reasonable to expect that two layers of geotextile and a geonet are more than sufficient to protect the geomembrane.

4. Geomembrane Thickness

EPA's July 6, 1999 Comment 28 on the Detailed Work Plan:

Figure 3: Define the thickness of the flexible membrane liner and sub base material. The EPA has recommended a 60 mil. flexible membrane.

EPA's April 27, 2000 Comment on August 12 Addendum:

The EPA recommended a 60-mil thick geomembrane. The response states that a 60-mil thick geomembrane will be provided. To avoid possible confusion in the future, the method used to determine the geomembrane thickness shall be defined. The material thickness can be specified as a minimum thickness or as an average thickness. Specifying a minimum thickness would result in the geomembrane being at least 60-mil thick, whereas specifying an average thickness of 60 mil would result in material with a minimum thickness of about 54 mils. It is likely that material with an average thickness of 60 mil is adequate for intended purpose.

GE Response:

A 60-mil, textured HDPE geomembrane was installed as part of the base liner system for the portion of the Building 71 OPCA constructed in 1999. Pre-construction conformance testing conducted on a single sample of the geomembrane upon delivery indicated an average geomembrane thickness of 65.9 mils. Manufacturing quality control procedures conducted by the geomembrane manufacturer, Solmax International, Inc., indicated an overall average thickness of 57.4 mils for all the geomembrane rolls delivered to the site. The geomembrane thickness testing results are provided in Attachment 3.

5. Leachate Generation (Geocomposite and Pipe Sizing)

EPA's July 6, 1999 Comment 32 on Detailed Work Plan:

Attachment A, Technical Drawings, A-5: Leachate pipes are shown which are 6-inch diameter with minimum slopes of 0.5%. No calculations are provided to substantiate pipe sizing or transmissivity of the drainage geocomposite for predicted leachate flows. In addition, pipe strength calculations

should be provided for Consolidation Area loading either at a final grade or due to vehicular and equipment loads during construction or operations.

EPA's April 27, 2000 Comment on August 12 Addendum:

BB&L performed three HELP model analyses in support of pipe sizing and geocomposite calculations. Based on the information presented, several issues need to be addressed in regard to HELP model analysis. The selection of material texture 8 (ML soil type by USCS) from the HELP default menu may not be sufficient. It is our understanding that the river sediment is predominately sandy; therefore, a more granular material selection may better represent the river sediment. As a matter of consistency, the HELP model identifies the river sediment as a silty soil (ML), whereas page 1 of the pipe wall thickness calculation identifies it as a "saturated silty sand and gravel."

The rationale for selecting the two scenarios to model worst-case conditions is not clear. The Agencies are of the opinion that the worst-case condition would occur when only small portion of the first lift of material has been placed in the consolidation area. Essentially, under this scenario, 100% of precipitation falling within the consolidation area footprint would need to be handled as leachate as there does not appear to be any provision for isolating "clean" rainwater from water that contacts in-place sediment. The scenarios presented address a time in the future after significant filling has occurred. For example, using Condition B, which in the Agencies' opinion more closely represents the worst-case scenario, the volume of leachate that the pipe must convey should be determined by multiplying the calculated percolation/leakage through layer 1 of 4.89 inches/day by the total area of landfill (AA + AB = 5.1 acres, as presented on page 2 of the leachate collection pipe size calculations in Appendix L). The resulting volume of leachate, Q_{total} becomes approximately 1.05ft³/sec versus 0.219ft³/sec presented in the calculations, more than a fourfold increase. The pipe sizing calculations shall be revised accordingly to address the worst-case condition not a condition at some time in the future. An alternative approach would be to design the piping system based on a design storm event. From drawing A-5, it appears that all leachate generated within the consolidation area must be discharged through a single pipe. Therefore, this pipe must be able to convey sufficient flow so as to prevent a head build-up within the consolidation area in excess of 12 inches.

In regard to the transmissivity calculations, a more appropriate model would include a geonet/geocomposite and a geomembrane. Output from such a model using version 3.07 of the HELP model (latest version) would yield the volume of drainage collected from the geonet/geocomposite, maximum head build-up above the geomembrane and the location of the maximum head build-up from the drain point. Based on the drainage collected from the geonet/geocomposite, the required transmissivity can be determined. Additionally, the maximum drainage length was determined to be approximately 200 feet in the southernmost drainage area of the consolidation area as shown on drawing A-5. The calculation shall be revised using a more appropriate HELP model.

The EPA requests that GE shall provide an estimate of the leachate volume likely to be generated by dewatering sediment due to consolidation of the material be considered in the above calculations. Even though consolidation soils from the river will be required to pass the "paint filter test", there will be some moisture that could contribute to leachate generation. This volume of leachate will be in addition to leachate generated by precipitation.

There appears to be a conflict between the drawings and the apparent intent of the leachate collection piping system. A pipe running in an east-west direction across the consolidation area is identified as a perforated pipe while the collection pipe running along the toe of the western berm appears to be a solid wall pipe (see drawing A-5). Details 1 and 2 on drawing A-8 seem to verify these materials and conditions. In this regard, please clarify how leachate will be collected from the two southerly drainage areas within the consolidation area and discharged from the area.

Depending on how the revised pipe sizing calculations are prepared, it may be practical to use various pipe diameters to transmit flow to the exit point.

In regard to geocomposite testing, the creep potential of the material shall be considered. The specification should require the geocomposite to retain a certain percentage of its original thickness after a specified time under a given load. Manufacturers may have data available from long-term tests that reflect the creep potential of their product(s). It is also recommended that transmissivity tests be performed using a number of hydraulic gradients in order to span the range of possible gradients. Increasing or decreasing the gradient may cause flow to become either turbulent or laminar, changing the flow characteristics of the geocomposite.

GE Response:

Several EPA comments within the topic are best addressed by first describing the approach that has been utilized to estimate reasonable "worst case" leachate generation potential. Based on the results of several iterative evaluations of leachate potential using the Hydrologic Evaluation of Landfill Performance (HELP) Model, it is anticipated that maximum potential leachate generation will occur prior to final closure of the Building 71 OPCA. The HELP Model establishes a moisture content for each soil type modeled within the program, thereby accounting for the overall residual moisture within the soils. It is difficult to specify a moisture content and to quantify reliable leachate generation rates for the individual consolidation materials that are subject to consolidation, since the moisture contents of the material will vary and the actual volumes of these materials will also vary. For example, all of the consolidation materials scheduled to be placed in the Building 71 OPCA during the 2000 construction season have been stockpiled and tarped, in some cases in heated buildings, allowing much of the residual water within the soil to drain prior to placement within the OPCA. In other cases, soils may be excavated from an area of remediation and immediately hauled and directly placed within the OPCA. Also, it should be noted that construction debris (e.g., brick, concrete, metal, etc.) with very low moisture contents will comprise a percentage of the final consolidation materials. Based on the above considerations, the input parameter within the HELP Model for the soil type associated with the consolidation material has been revised to incorporate an overall and representative USCS soil type SM (i.e., silty sand). Using this soil type to represent the overall composition of the consolidation materials, it is not necessary to calculate separate leachate generation rates for the sediments (or any other specific materials) to be consolidated at the Building 71 OPCA. In addition and as indicated above, such calculations would not produce meaningful leachate estimates.

The leachate calculations previously provided in the Addendum were based on the assumption that the OPCA would be constructed in three separate "phases" with consolidation activities occurring in one area while an adjoining area was under design or construction. These calculations have since been refined to incorporate the portion of the OPCA constructed in 1999 to support the sizing of pumps for the leachate collection manhole that was recently modified, as described in a letter from GE to

EPA, dated March 23, 2000. The modified calculations are presented in Attachment 4. With a phased OPCA construction, the maximum leachate generation would occur under the following scenario:

- Approximately 75% (3.1 acres) of the final OPCA has been constructed and filled to its capacity;
- No portion of this area has received a final (impermeable) cap;
- Approximately 60% of the 3.1 acre area has an interim soil layer with established vegetative cover;
- The remaining filled area has an interim soil cover but is without an established vegetative cover; and
- The remaining 25% (1.0 acre) of the total OPCA is empty and contains no consolidation material, with no runoff allowed from the cell.

The pipe sizing calculations previously presented in the Addendum have been re-evaluated to account for the scenario mentioned above, and are provided in Attachment 4. The calculations indicate that a 6-inch diameter pipe is adequate in handling the leachate attributable to the worst-case condition.

The transmissivity of the geosynthetic drainage composite (GDC) was also re-evaluated using HELP Model (Version 3.07) and included the GDC and the underlying geomembrane to determine the required GDC transmissivity based on a maximum head condition of 12 inches of leachate above the geomembrane. As a result of the HELP Model evaluation, a GDC having a minimum transmissivity of 1.5×10^{-3} m²/sec was required for use in the Building 71 OPCA liner system. Pre-construction transmissivity testing performed by AGP Laboratories, Inc. on a representative sample of the GDC installed within the Building 71 OPCA in 1999 is included in Attachment 4. As can be seen from the test results, the GDC attains the required transmissivity under conditions similar to the anticipated final OPCA conditions.

Regarding EPA's assertion of a conflict between the drawings and the apparent intent of the leachate collection piping system, it should be noted that the pipe running along the toe of the western berm is a perforated pipe. The reference on Sheet A-5 of the Detailed Work Plan is referring to the solid-wall section of pipe within the berm (i.e., outside of the base liner system limits). Detail 5 on Sheet A-8 is correct as shown; Detail 2 on Sheet A-8 should have further indicated that the pipe was perforated. Leachate will be collected within the two perforated leachate collection pipe networks and will be discharged into the collection manhole via a solid wall pipe outside the limits of the lined area.

Long-term testing of creep potential of a GDC using a specific liner system configuration and the expected loads and gradients at a site is not typically a standard testing requirement or specification for the GDC, since results are not available for years. A seating time of two hours was required for the pre-construction conformance testing of the GDC used in 1999 at the Building 71 OPCA. It is important to bear in mind that given the size and height restrictions for the Building 71 OPCA (i.e., a maximum height of approximately 30 feet, and a size of approximately 4 acres), the loading

conditions are significantly less than those for typical landfill disposal facilities for which most of the testing is performed. Literature and information on creep potential available from the manufacturers and independent research indicate that long-term creep under the loading conditions and gradients associated with the Building 71 OPCA is not a significant design factor.

6. Veneer Stability

EPA's July 6, 1999 Comment 33 on Detailed Work Plan:

Provide calculations to demonstrate that adequate veneer stability exists between the respective interface layers of the components of the final cover systems on the 33% slope. The calculated requirements should be verified using proposed materials by testing in accordance with ASTM D-5321. The tests to evaluate the interface friction requirements may include Koerner, Hwu, Giroud, Bachus and Bonabarte methods.

EPA's April 27, 2000 Comment on August 12 Addendum:

The veneer slope stability analysis presented to address EPA Comment 33 is only partially complete. The analysis does not include the influence of potential seepage head build-up within the cover soils on the consolidation area sideslopes. It is recommended that a fully saturated condition be evaluated given the potential for the formation of ice dams at the toe-of-slope or ice lenses within the drainage composite on the sideslopes due to a thickness of cover soil less than the anticipated frost depth for the location. The formation of ice dams and/or frost lenses could cause water to pond within the cover soil, thus inducing destabilizing hydrostatic forces (NAVFAC DM-7.1 suggests an extreme frost depth for the location of approximately 50 inches). The analysis shall be revised to include this condition. A procedure presented by Giroud, Bachus and Bonaparte can be used to evaluate veneer stability considering seepage forces.

The cohesive strength value of 50 psf should be justified/clarified. Is this value internal to the soil mass or is it actually an adhesion value between the cover soil and the upper geotextile of the drainage composite? Will the project specifications require the cover soil to have a cohesive strength of not less than 50 psi? GE shall perform direct shear tests in accordance with ASTM D-5321 on all critical interfaces.

Based on Figure 3 of Attachment K, it appears the geomembrane will be placed directly on natural (soil) materials. This being the case, the potential for slippage between the geomembrane and the soil material should be evaluated. Slippage between the geomembrane and the underlying soil material could result in tensioning of the geomembrane and possible failure of the material.

GE Response:

The issue of veneer stability along the steeper (i.e., 33%) slope of the final OPCA cap is discussed in the response to the next EPA comment (Comment 36).

With respect to the cohesive strength used on the veneer stability calculations conducted to date, the cohesive strength value of 50 psf in the calculations refers to the adhesion between the nonwoven geotextile of the GDC and the textured HDPE. This interface is considered to be one of the most

susceptible to a potential failure. As shown in a figure from the 1993 Geosynthetics Conference Proceedings (refer to Attachment 5), direct shear tests of this interface reveal typical friction angles of 21 degrees and cohesion factors of approximately 500 psf. Since adhesion can be difficult to quantify, a conservative value of 50 psf was used in the analyses, which is approximately 10 percent of the laboratory value. This approach accounts for adhesion without overestimating its importance on the stability of the slope. GE will also perform direct shear testing in accordance with ASTM D-5321 on the critical interface(s) as part of the pre-construction testing program for final cover installation. At that time, the actual construction materials (soils and geosynthetics) to be used during final cover installation will be tested.

Stability calculations for the interface between the consolidation material and the textured geomembrane component of the final cover system are also included in Attachment 5.

7. Frost Damage

EPA's July 6, 1999 Comment 36 on Detailed Work Plan:

As previously commented, there are no calculations provided to substantiate that the proposed thickness (e.g., min. 2 feet) of the final cover system will provide adequate protection from frost damage of the underlying geosynthetics. The preferred method to evaluate the frost protection issue is the Modified Berggren Equation.

EPA's April 27, 2000 Comment on August 12 Addendum:

The Agencies acknowledge receipt of several articles related to frost damage of geosynthetics. In general, the articles suggest that geosynthetics are not susceptible to frost damage. A concern not addressed by the articles directly is the potential for water to freeze within the drainage composite, subsequently resulting in a potential increase in hydrostatic pressure within the protective cover soil which could result in cover soil instability. In an article provided to BB&L by Carmo Environmental Systems, Inc. from a draft EPA document, the following statement is presented:

"It is advisable to prevent the drainage layer (if one is present) from freezing as well, particularly on relatively steep side slopes. If the drainage layer freezes, its function is destroyed for part of the year. During the thaw period, it is particularly important that the drainage layer function properly, i.e., drain from the toe, and that the protection layer be sufficiently thick to provide the protection that is required."

In light of this statement, the Agencies strongly recommend that BB&L re-evaluate the cover soil thickness and potential veneer instability of the cover soil mass.

GE Response:

In response to this comment, GE has evaluated the potential for the formation of ice dams within the final cap drainage layer, subsequent saturation of the overlying soil layer, and a reduced veneer stability. To perform this evaluation, the thickness of saturated soils above the drainage layer was first estimated using the HELP Model (Version 3.07) assuming that the drainage layer was frozen

and unable to transmit water. The HELP modeling results are presented in Attachment 6. As can be seen in the modeling output, using climatological parameters for western Massachusetts, the average annual head developed on the geomembrane is approximately one inch, the average peak daily head on the geomembrane is approximately 8 inches, and the maximum peak daily head on the geomembrane is approximately 14 inches.

Slope stability calculations performed incorporating a 14-inch thick saturation zone indicate a factor of safety of approximately 1.2 (refer to Attachment 6). This safety factor is acceptable for temporary or short-term conditions, especially when considering the conservative nature of the input parameters and calculations. Also, a 14-inch saturation zone is not likely because, of the average total annual precipitation amount for western Massachusetts (48.7 inches) used within the model to develop the head calculations, only 16.4 inches (or approximately 34%) of the precipitation falls during months when the average monthly temperature is below 32° F (i.e., November through February). It should be noted that some of the key model input parameters are necessarily assumptions (e.g., slope angles, surface and porewater drainage lengths, hydraulic conductivities, etc.) that may be refined during the final cover system design to be developed in the upcoming years. Where reasonable during the design, the slope angles, drainage lengths, and hydraulic conductivities will be optimized to increase safety factors.

With regard to the formation of ice lenses within the drainage layers and ice dams at the toe-of-slope, it is not expected that isolated lenses of ice within the GDC or overlying sand layer will have a significant effect on the overall drainage of the final cover system. Also, at this time, it is expected that the majority of the final cover porewater drainage system will drain into perforated subsurface piping located within anchor trenches (anticipated to be approximately 3 to 4 feet below final surface elevations) at the toe of the slope, with the number of discharge locations exposed to atmospheric conditions (i.e., to freezing temperatures) minimized. Once the final cap configurations are better understood, it may be possible to place additional cover material over the trenches at the toe of the slope, thereby providing additional frost protection in these critical areas. Also, the discharge locations for the porewater drainage system will be located as far from the toe of the landfill as possible to minimize the potential for freezing of porewater and the creation of ice dams at the toe.

8. Geophysical Survey, Hill 78 OPCA

EPA's April 27, 2000 Comment on August 12 Addendum:

In general, GE needs to provide additional information concerning the proposed geophysical survey along the perimeter of the Hill 78 Landfill. The following is a list of specific comments concerning the proposed geophysical surveys:

With regard to surveying a 50-foot-wide strip, it is recommended that the coverage be expanded to a 200-foot-wide strip with approximately 100 feet of the survey area located either side of the area subject to consolidation. This will enhance the lateral resolution of the boundary.

The Addendum to the June 1999 Work Plan includes surveying a 25-foot by 25-foot area, centered on H78B-8R. GE did not specify the geophysical methods (EM-31/61, Mag, and/or GPR) they propose to use at H78B-8R.

How will the survey be designed (transects perpendicular to axis of boundary, intervals between transects)?

Fifty-foot transects should be extended as needed (based on field readings) to obtain sufficient data on either side of the area subject to consolidation.

GE shall submit a written proposal and obtain Agency approval for the geophysical survey 30 days prior to the initiation of field work. The geophysical survey must be completed prior to the Hill 78 OPCA expanding south of the current access road.

GE Response:

At the May 3, 2000 meeting, EPA confirmed that the geophysical survey should be conducted over a 50-foot-wide band along the perimeter of the Hill 78 OPCA (as previously agreed between EPA and GE), rather than the 200-foot-wide band recommended in EPA's April 27, 2000 comments. Also, it was agreed that the 25-foot by 25-foot area centered around H78-8R will be surveyed using Geonics EM-31 instrumentation. Also discussed and agreed upon at the May 3, 2000 meeting, EPA's remaining comments relating to the geophysical survey will be addressed in a future proposal to be submitted to EPA and MDEP before the geophysical survey is performed. As presented in the Addendum, the timing of the survey will be such that it will be performed prior to any material placement in the area of interest (i.e., the 50-foot-wide band).

9. Future Groundwater Monitoring - Hill 78 and Building 71 OPCAs

EPA's April 27, 2000 Comment on August 12 Addendum:

Three additional wells on the eastern side of the General Dynamics parking lot (Unkamet Brook - Building OP-2 area) shall be added to the groundwater level-monitoring program to provide additional groundwater flow data east of the Consolidation Areas. No additional groundwater sampling would be necessary.

GE Response:

During the May 3, 2000 meeting, EPA agreed that these additional wells would not be necessary.

EPA's April 27, 2000 Comment on August 12 Addendum:

On Figure 3, GE shows a groundwater flow trough southwest of the Hill 78 Landfill. The area is dashed on the map due to limited well monitoring in that area. This map shows the potential for contaminants from the landfill and especially well H78B-8R to move preferentially in that direction - undetected by the proposed well monitoring network. EPA may require additional wells in that location based upon the results of the geophysical survey and other design factors e.g., groundwater mounding, etc..

GE Response:

GE will evaluate groundwater flow (and potential changes due to groundwater mounding) in this area following the collection of additional data as part of the OPCA groundwater monitoring program

and/or the baseline groundwater monitoring program for the Plant Site 3 Groundwater Management Area (GMA), which includes the OPCAs.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 2.2. Review the well installation logs presented in Appendix A and the top of till contours presented in Attachment C. The comparison of these data indicates that the OPCA monitoring wells are either not screened within a confining layer or within till. Therefore, dense non-aqueous phase liquids, if present, would likely not be detected by the monitoring program. GE shall propose a strategy for resolving this discrepancy.

GE Response:

As discussed with EPA, GE will submit to EPA within the next few months a proposal for DNAPL-related investigations in the OPCA area. That proposal will identify the scope and timetable for further investigations related to this topic.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Table 3. Provide a note indicating whether or not samples were filtered or unfiltered. Also, the inorganic analytes listed on Table 3 include only arsenic, barium, and zinc. GE shall present the results for the remaining inorganic analytes required by Appendix IX +3 analysis.

GE Response:

Unfiltered samples were collected during the baseline sampling round. During future rounds, both filtered and unfiltered samples will be collected for PCB and inorganics analyses (as stated on Page 3-1 of Attachment B to the Addendum), in accordance a revised version of GE's Field Sampling Plan/Quality Assurance Project Plan (FSP/QAPP) (which is currently under development in response to EPA's April 11 and April 20, 2000 comments on the FSP/QAPP submitted in January 2000.

All detected inorganics were presented on the tables included in the Addendum. Analytical data for the remaining inorganic analytes (i.e., detection limits) are contained on the attached data sheets (see following comment and response).

EPA's April 27, 2000 Comments on August 12 Addendum:

Appendix B, Section 2.5, Page 2-3. GE shall provide copies of the laboratory analytical data sheets, along with a quality assurance/quality control (QA/QC) summary report indicating whether or not the analytical data meet the QA/QC requirements set forth by GE's Revised Sampling and Analysis Plan/Data Collection and Analysis Quality Assurance Plan, October 1998 (pending revisions).

GE Response:

The laboratory data sheets are provided within Attachment 7. GE's previous Sampling and Analysis Plan/Data Collection and Analysis Quality Assurance Plan (dated October 1998) has been extensively revised and was submitted to EPA and MDEP in January 2000 as a FSP/QAPP. That FSP/QAPP is currently being revised further in response to recent (April 11 and April 20, 2000)

EPA comments. After that revised FSP/QAPP has been finalized, the QA/QC summary report requested by EPA in this comment will be submitted.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.2, Page 3-1. GE indicates that both filtered and unfiltered groundwater samples will be collected for PCB and metal analyses. Were both unfiltered and filtered samples collected during the baseline monitoring program for PCBs and metals? Subsequent groundwater monitoring events should be consistent to ensure proper comparisons of data.

GE Response:

As noted above, only unfiltered samples were collected during the baseline sampling round. During future rounds, both filtered and unfiltered samples will be collected for PCB and inorganics analyses, in accordance with GE's revised FSP/QAPP (currently under development).

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.2, Page 3-1. GE shall sample all OPCA monitoring wells for PCDDs/PCDFs. Insufficient data have been collected to date to exclude analysis of these parameters at all OPCA monitoring wells.

GE Response:

GE will sample all OPCA monitoring wells for PCDDs/PCDFs until sufficient data have been collected to justify exclusion of these parameters from future analyses.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.4, Page 3-2, 3rd Paragraph. GE shall provide a rationale for why a Method 2 GW-2 standard should not be developed subject to EPA approval.

GE Response:

As discussed on the cited page of the Addendum, GE will initially use the Method 1 GW-2 standards specified in the Massachusetts Contingency Plan (MCP) to evaluate GW-2 groundwater. As also explained on that page, the baseline groundwater sampling for the OPCAs detected no volatile organic compounds (VOCs) in groundwater; but if future monitoring detects, in GW-2 groundwater, VOCs for which there are no Method 1 GW-2 standards, GE will develop a Method 2 GW-2 standard for each such constituent using procedures specified in the MCP or approved by EPA, or will provide a rationale for why such a standard should not be developed. This approach is consistent with the approach specified in Attachment H to the *Statement of Work for Removal Actions Outside the River (SOW)* (which is Appendix E to the Consent Decree). GE agrees that any such Method 2 GW-2 standard developed will be "subject to EPA approval."

EPA's April 27, 2000 Comment to August 12 Addendum:

Appendix B, Section 3.4, Page 3-2, 4th Paragraph. GE shall present its rationale to EPA for why a Method 2 GW-3 standard was not developed subject to EPA approval.

GE Response:

As discussed in Section 3.4, GE will initially use the MCP's Method 1 GW-3 standards to evaluate GW-3 groundwater. Section 3.4 then addresses the handling of compounds detected in GW-3 groundwater for which Method 1 GW-3 standards do not exist (or alternative standards have not been approved by EPA). It notes that no such compounds were detected during the baseline groundwater sampling for the OPCAs. It also indicates that if such compounds are detected in the future, GE will not develop Method 2 GW-3 standards, as part of the OPCA monitoring program, unless such compounds are shown to be attributable to the consolidation activities. However, Attachment H to the SOW provides that, as part of the general baseline monitoring program for the GMA that includes these areas (the Plant Site 3 GMA), if compounds are detected in GW-3 groundwater for which Method 1 GW-3 standards do not exist (or alternative standards have not been approved by EPA), GE will develop Method 2 GW-3 standards using procedures specified in the MCP or approved by EPA, or provide a rationale for why such standards should not be developed. In any case, GE agrees that if Method 2 GW-3 standards are developed (either because the constituents are shown to be attributable to consolidation activities or as part of the baseline monitoring program for the Plant Site 3 GMA), such standards will be "subject to EPA approval."

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.4, Page 3-2, 5th Paragraph. Consistent with Attachment H to the SOW, the site-specific risk evaluation shall consider EPA or MCP risk assessment guidance.

GE Response:

GE concurs that any site-specific risk evaluation supporting alternative risk-based GW-2 or GW-3 standards will consider appropriate EPA and/or MDEP risk assessment guidance, as provided in Attachment H to the SOW.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, NAPL performance standards need to be developed to address NAPL if detected in the OPCA monitoring well network.

GE Response:

The OPCA groundwater monitoring program is not designed to be a NAPL monitoring program. As stated in Section 3.3, second paragraph, should any new occurrences of NAPL be observed, subsequent activities will be conducted under the procedures outlined in Attachment H to the SOW and any other approved procedures established for the groundwater monitoring program for the Plant Site 3 GMA once that program has been implemented. Section 2.7 and Attachment H of the SOW set forth the Performance Standards for NAPL for the overall GE-Pittsfield/Housatonic River Site.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.5, Page 3-3, 2nd Paragraph. The notification requirements for GW-2 groundwater exceedances do not apply to the OPCA monitoring. There are no and will not be any school or residential structures within 30 feet of any OPCA monitoring point. GE shall propose and obtain the Agencies' approval for a more practical notification requirement.

GE Response:

The cited paragraph in Section 3.5 acknowledged that there are no current OPCA monitoring wells within 30 feet of a school or residence, but provided certain notification requirements for GW-2 exceedances in such wells in the event that such wells are installed in the future in response to data obtained from a GW-2 sentinel well. If no OPCA monitoring wells are installed within 30 feet of a school or residence, these notification requirements will not apply. Separate notification requirements are already provided in Section 3.5 for exceedances of GW-2 standards in GW-2 sentinel wells, as well as for exceedances of GW-3 performance standards and UCLs.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.5, Page 3-4. Exceedance of a UCL would likely indicate a "statistically significant increase" in dissolved-phase constituent for any OPCA monitoring well, and therefore, GE shall perform the same activities identified for statistically significant increases in dissolved-phase constituents. Revise the beginning of the 4th paragraph on page 3-4 as follows: "If a statistically significant increase or UCL exceedance..."

GE Response:

GE agrees to conduct the same activities specified in the cited paragraph on page 3-4 in the event that a UCL exceedance is identified.

EPA's April 27, 2000 Comment on August 12 Addendum:

Appendix B, Section 3.7, Page 3.5. Any proposed modifications to the monitoring program are subject to EPA approval.

GE Response:

Agreed.

1999 Stormwater Basin Design

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: BMS Date: 05-01-00
TITLE: Engineering Design Calculations Reviewed By: _____ Date: _____
SUBJECT: OPCA - 1999 Stormwater Basin Design

OBJECTIVE:

Calculate the required storage capacity for the 1999 stormwater basin and determine stormwater runoff conditions for the 1999 stormwater basin watershed based on pre- and post-developed OPCA conditions. Use TERRAMODEL to develop and route the inflow hydrograph for the 1999 stormwater basin to determine design capacity, outflow hydrographs, and peak outlet conditions during the 25-year, 24-hour design storm. Determine the required diameter and slope for the 1999 stormwater basin outlet pipe.

REFERENCES:

1. Technical drawings and figures contained in the Detailed Work Plan for On-Plant Consolidation Areas prepared by Blasland, Bouck & Lee, Inc. (BBL), dated June 1999 (Work Plan).
2. TERRAMODEL Version 9.60 computer terrain modeling and hydrology program developed by Plus 3/Spectra Precision (watershed hydrograph modeling performed by hydrology module resident within TERRAMODEL based on Technical Release-20 [TR-20] methodology).

4. Quick TR-55 Urban Hydrology for Small Watersheds Version 5.47 (DOS) computer-based implementation of the Soil Conservation Service's TR-55 methodology, Haestad Methods, Inc..

METHODOLOGY:

The design of the 1999 stormwater basin assumes that the basin must provide sufficient storage capacity to limit post-developed peak stormwater discharge from the stormwater basin watershed to pre-development conditions during the 25-year, 24-hour storm. Consequently, the configuration of the 1999 stormwater basin is dependent on the maximum allowable discharge from the basin and the rate of stormwater runoff entering the basin under post-development conditions. The rate of stormwater runoff entering the 1999 stormwater basin is determined from a runoff hydrograph generated using TR-20 methodology and the TERRAMODEL hydrology module. The following is used to determine the runoff hydrograph, the configuration of the 1999 stormwater basin, and the stormwater basin outflow hydrograph.

1. Stormwater modeling parameters used in TERRAMODEL are determined based on the following conditions:
 - Hydrologic soil group B for undisturbed areas (i.e., all pre-development watershed areas and areas of the post-developed watershed not affected by construction activities);
 - Hydrologic soil group C for developed watershed areas;
 - Runoff curve numbers (from TR-55):
 - Pre-developed areas covered by woods-grass combination (poor hydrologic condition) = 73
 - Unpaved roads for pre-developed areas = 82
 - Post-developed OPCA areas (grassland, fair hydrologic condition) = 79
 - Impervious areas such as the General Dynamics parking lot and the area covered by the 1999 stormwater basin during the approximate design high water stage = 98;
 - Rainfall depths:
 - 2 year/24 hour = 2.86"
 - 25 year/24 hour = 5.05";
 - Pre- and post-developed areas of stormwater basin watershed (delineated based on the technical drawings entitled "Subgrade Plan" and "Existing Site Plan" and the figure entitled "Final Configuration of On-Plant Consolidation Areas" contained in the Work Plan; and
 - Times of concentration (Tc) calculated using Quick TR-55 for pre- and post-developed stormwater basin watershed conditions.

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: BMS Date: 05-01-00
 TITLE: Engineering Design Calculations Reviewed By: _____ Date: _____
 SUBJECT: OPCA - 1999 Stormwater Basin Design

2. Stormwater inflow hydrographs are computed for the pre- and post-developed OPCA condition using the TERRAMODEL hydrology module. The pre-development hydrograph is used as a baseline for comparison with post-developed runoff conditions and to establish the maximum allowable discharge from the 1999 stormwater basin. The post-development hydrograph is used to determine size requirements and performance characteristics for the 1999 stormwater basin.
3. A rating curve (stage/storage/discharge) is developed for the 1999 stormwater basin using the TERRAMODEL hydrology module.
4. The post-development inflow hydrograph is routed through the 1999 stormwater basin using the TERRAMODEL hydrology module to produce a stormwater basin outflow hydrograph. The design conditions for the 1999 stormwater basin assume the following:
 - Water level in the stormwater basin is at the invert elevation of the low flow orifices at the beginning of a storm event; and
 - 2-inch diameter low flow orifices in the concrete outlet structure are modeled as 1-inch diameter orifices to account for the reduction in flow capacity caused by the presence of riprap at the upstream end of the orifices.
5. The design of the stormwater basin outlet pipe is based on the peak stormwater basin discharge during the 25-year, 24-hour storm.

CALCULATIONS:

Supporting calculations, including output from Quick TR-55 and TERRAMODEL, are included as attachments.

1. TERRAMODEL Hydrology Input Parameters

The table below presents a summary of the input parameters required by the TERRAMODEL hydrology module to develop runoff hydrographs for pre- and post-developed conditions. Under the post-developed condition, the stormwater basin watershed is divided into two subareas (i.e., "Development" and "Bypass") as only the stormwater runoff from the "Development" subarea is routed through the 1999 stormwater basin. The "Bypass" subarea comprises a portion of the General Dynamics parking lot where runoff is conveyed through a relocated storm sewer pipe to a point that is downgradient of the 1999 stormwater basin. Although it does not contribute runoff to the basin, the "Bypass" subarea is still considered part of the 1999 stormwater basin watershed simplifying the comparison of pre- and post-development runoff conditions. The post-development runoff condition is obtained by combining the peak discharge from the two subareas.

Condition	Subarea	Watershed Area (acres ±)	Composite Curve Number, CN	Time of Concentration, Tc (hours)	25-Yr/24-Hr Precip. (in)
Pre-developed	Pre-development	8	85	0.27	5.05
Post-developed	Development	4.4	82	0.37	5.05
Post-developed	Bypass	3.2	98	0.17	5.05

2. Runoff Hydrograph for 1999 Stormwater Basin Watershed (TERRAMODEL Hydrology Output)

The table below presents the peak discharges from the stormwater basin watershed subareas for pre- and post-developed

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: BMS Date: 05-01-00
 TITLE: Engineering Design Calculations Reviewed By: _____ Date: _____
 SUBJECT: OPCA - 1999 Stormwater Basin Design

conditions.

Condition	Subarea	25-Yr/24-Hr Storm Peak Discharge (cfs)
Pre-developed	Pre-development	23.3
Pre-development Total:		23.3
Post-developed	Development	10.7
	Bypass	12.8
Post-development Total:		23.5

Development of the 1999 stormwater basin watershed increases peak stormwater runoff for the design storm by 0.2 cfs (about 1%). This increase in peak runoff is compensated for by routing runoff from the "Development" subarea through the 1999 stormwater basin.

3. Rating Curve

The rating curve developed for the 1999 stormwater basin is based on the basin configuration as depicted in the technical drawing entitled "Subgrade Plan" contained in the Work Plan. The rating curve is determined using TERRAMODEL and is based on the planimetric area of the elevation contour lines within the 1999 stormwater basin. The rating curve for the 1999 stormwater basin represents storage volumes contained at various stages between the invert of the low flow orifices (elev. 1008.0) and the lowest crest elevation of the basin berm (elev. 1012.7).

4. Hydrograph Reservoir Routing

The generated runoff hydrograph for the "Development" subarea of the post-developed watershed is routed through the stormwater basin using the rating curve (stage/storage/discharge) described above. Results of the routing calculations are as follows:

Subarea	25-Yr/24-Hr Storm Peak Inflow (cfs)	25-Yr/24-Hr Storm Peak Routed Outflow (cfs)	25-Yr/24-Hr Storm Peak Water Elevation (ft)
Development	10.7	6.9	1011.5

The combined post-developed peak discharge for the 1999 stormwater basin watershed is 19.7 cfs (6.9 cfs for the "Development" subarea after routing through the basin plus 12.8 cfs for the "Bypass" subarea), which represents a 3.6 cfs decrease (about 15%) in peak discharge as compared to pre-developed conditions. Finally, the peak water elevation presented above provides for a minimum 12-inches of freeboard to the crest of the basin berm.

5. Basin Outlet Pipe

The basin outlet pipe is sized to convey the estimated peak discharge (6.9 cfs) from the 1999 stormwater basin during the 25-year, 24-hour design storm. Since the capacity of the basin outlet pipe may be impacted by a tailwater condition in downstream manhole MH-5, an oversized pipe diameter is proposed. A 15-inch diameter PVC pipe laid on a 2.8% slope has a capacity of 16 cfs, which is more than twice the expected peak discharge from the basin during the 25-year, 24-hour storm. An analysis of the outlet pipe

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: BMS Date: 05-01-00
TITLE: Engineering Design Calculations Reviewed By: _____ Date: _____
SUBJECT: OPCA - 1999 Stormwater Basin Design

indicates that a slope of 0.51% slope is required for a 15-inch diameter PVC pipe to convey 6.9 cfs. Consequently, the proposed outlet pipe can convey the required 6.9 cfs peak basin discharge with a tailwater condition approximately 0.82 feet above the crown of the basin outlet pipe. Although not considered in this analysis, any headwater condition would tend to increase the flowrate through the outlet pipe.

SUMMARY:

Development of the consolidation areas will increase peak stormwater runoff from the 1999 stormwater basin watershed by about 1% during the 25-year, 24-hour storm. However, by routing the runoff from a portion of the watershed through the 1999 stormwater basin, peak runoff from the 1999 stormwater basin watershed is reduced by about 15% compared with pre-development conditions. Since these calculations are based on an assumed post-development watershed configuration (acreage, slopes, drainage ditch layout, etc.) for the 1999 stormwater basin, the actual stormwater basin inflow and outflow hydrographs may differ slightly from those presented in this document.

- NOTES:**
1. BASE MAP INFORMATION SHOWN ON THIS DRAWING WAS DEVELOPED FROM FIELD SURVEY DATA OBTAINED BY BLASLAND, BOUCK & LEE, INC. ON FEBRUARY 10, 1999. CONDITIONS SHOWN ARE APPROXIMATE ONLY DUE TO SNOW AND ICE ACCUMULATIONS EXISTING AT TIME OF SURVEY.
 2. ELEVATIONS SHOWN ARE REFERENCED TO NATIONAL GEODETIC VERTICAL DATUM (NGVD) 1929.
 3. HORIZONTAL DATUM IS REFERENCED TO THE MASSACHUSETTS STATE PLANE COORDINATE SYSTEM (NAD 1927).
 4. CONTOUR INTERVAL EQUALS 1 FOOT.
 5. DIFFERENCES NOTED BY THE CONTRACTOR BETWEEN BASE MAP INFORMATION AND ACTUAL SITE CONDITIONS, WHICH MAY AFFECT THE DESIGN CONFIGURATION, SHALL BE SUBMITTED TO GE. MODIFICATIONS MAY BE MADE TO THE DESIGN CONFIGURATION DURING PERFORMANCE OF THE SITE WORK AT THE DISCRETION OF GE.
 6. CONTRACTOR SHALL VERIFY THE PRESENCE AND LOCATION OF ALL ABOVE GROUND AND UNDER GROUND SITE FEATURES IN THE VICINITY OF PROPOSED CONSTRUCTION ACTIVITIES PRIOR TO COMMENCEMENT OF SITE WORK. ADDITIONAL SITE FEATURES MAY BE PRESENT WHICH ARE NOT SHOWN ON THIS DRAWING. IT SHALL BE THE CONTRACTOR'S RESPONSIBILITY TO COORDINATE WITH GE TO DETERMINE THE PRESENCE AND LOCATION OF SUCH FEATURES SHOULD THEY EXIST AND THE LOCATION OF ON-SITE EASEMENTS LEASE LINES AND RIGHT-OF-WAYS.
 7. INFORMATION REGARDING SITE SURVEY CONTROL WILL BE PROVIDED BY GE FOR CONTRACTOR USE PRIOR TO COMMENCEMENT OF SITE WORK. IT SHALL BE THE CONTRACTOR'S RESPONSIBILITY FOR ESTABLISHING AND MAINTAINING CONSTRUCTION SURVEY CONTROL DURING PERFORMANCE OF THE CONTRACT WORK.
 8. CONTRACTOR SHALL ASSUME EXISTING FENCING AT PERIMETER OF SITE IS GE'S PROPERTY LINE. NO WORK SHALL BE PERFORMED OUTSIDE THE PROPERTY LINE WITHOUT GE'S PRIOR APPROVAL. GE WILL OBTAIN APPROVALS FOR ANY WORK WITHIN IDENTIFIED LEASE OR EASEMENT AREAS.
 9. CONTRACTOR SHALL PROVIDE ALL LOCAL (NON-ENVIRONMENTAL) PERMITS AND MAKE ARRANGEMENTS FOR LOCAL INSPECTIONS (AS NECESSARY).
 10. CONTRACTOR SHALL FURNISH AND PLACE PROPER GUARDS FOR PREVENTION OF ACCIDENTS, PROVIDE ALL TRENCH SHORING, SCAFFOLDING, SHIELDING, DUST/FUME PROTECTION, SAFETY RAILINGS, BARRIERS, OR OTHER SAFETY FEATURES REQUIRED. THE CONTRACTOR SHALL PROVIDE AND MAINTAIN SUFFICIENT LIGHTS DURING NIGHT HOURS TO SECURE SUCH PROTECTION.
 11. CONTRACTOR SHALL BE SOLELY RESPONSIBLE FOR INITIATING, MAINTAINING, AND SUPERVISING ALL SAFETY PRECAUTIONS AND PROGRAMS IN CONNECTION WITH THIS CONTRACT. THE CONTRACTOR SHALL TAKE ALL NECESSARY PRECAUTIONS FOR THE SAFETY OF, AND SHALL PROVIDE THE NECESSARY PRECAUTION TO PREVENT DAMAGE, INJURY, OR LOSS TO ALL EMPLOYEES ON THE WORK AND ANY OTHER PERSONS WHO MAY BE AFFECTED THEREBY.
 12. EXISTING SURFACES OR FEATURES NOT SPECIFIED FOR MODIFICATION THAT ARE DAMAGED OR DESTROYED AS A RESULT OF WORK PERFORMED UNDER THIS CONTRACT SHALL BE RESTORED BY THE CONTRACTOR TO THEIR PRECONSTRUCTION CONDITION IN A TIMELY MANNER.
 13. ALL CONTRACTOR RELATED ACTIVITIES SHALL BE PERFORMED IN A MANNER WHICH ALLOWS FOR ALL NECESSARY OPERATING ACTIVITIES ASSOCIATED WITH THE U.S. GENERATING COMPANY AND GENERAL DYNAMIC COMPANY FACILITIES. ANY WORK DEEMED NECESSARY WHICH MAY AFFECT THOSE FACILITIES SHALL BE BROUGHT TO THE ATTENTION OF GE PRIOR TO COMMENCEMENT OF SUCH WORK. GE SHALL PROVIDE THE CONTRACTOR WITH AUTHORIZATION TO PROCEED PROVIDED GE AND THE AFFECTED PARTY(S) DEEM THE ACTION NECESSARY AND ACCEPTABLE.
 14. LEASE AND EASEMENT LINE LOCATIONS SHOWN ON THIS DRAWING DERIVED FROM PLAN PREPARED BY DESIGN GROUP, INC. ENTITLED "PLAN OF LAND SURVEYED FOR GENERAL ELECTRIC COMPANY", DATED FEBRUARY 18, 1993 (PROJECT NO. 930004) AND ARE APPROXIMATE ONLY.

Summary of Peak Discharges

PROJECT: X:\TMPROJ\201\20185\20185C.pro

 HYDROLOGIC REPORT - SUMMARY OF PEAK FLOW RATES

BASIN: OPCA

ID: 1999 STORMWATER BASIN

PREDEVELOPMENT

AREA = 8.00
 AVERAGE BASIN SLOPE = 0.00
 HYDRAULIC LENGTH = 0.00
 TIME OF CONCENTRATION = 0.27
 BASIN CURVE NUMBER = 85.00

DEVELOPMENT

AREA = 4.40
 AVERAGE BASIN SLOPE = 0.00
 HYDRAULIC LENGTH = 0.00
 TIME OF CONCENTRATION = 0.37
 BASIN CURVE NUMBER = 82.00

BYPASS

AREA = 3.20
 AVERAGE BASIN SLOPE = 0.00
 HYDRAULIC LENGTH = 0.00
 TIME OF CONCENTRATION = 0.17
 BASIN CURVE NUMBER = 98.00

Frequency (years)	Pre-developed Peak Q (cfs) ①	By-pass area Peak Q (cfs) ②	Developed Peak Q (cfs) ③	Allowable peak Peak Q (cfs) ④
25	23.3	12.8	10.7	10.5

- ① PRE-DEVELOPED PEAK Q IS THE PEAK STORMWATER RUNOFF FROM THE 1999 STORMWATER BASIN WATERSHED BEFORE CONSOLIDATION AREA DEVELOPMENT.
- ② BYPASS AREA PEAK Q IS THE PEAK STORMWATER RUNOFF FROM THE BYPASS SUBAREA. SINCE THIS SUBAREA IS NOT AFFECTED BY CONSOLIDATION AREA DEVELOPMENT, THIS PEAK RUNOFF IS VALID FOR BOTH PRE- AND POST-DEVELOPMENT CONDITIONS.
- ③ DEVELOPED PEAK Q IS THE PEAK STORMWATER RUNOFF FROM THE DEVELOPMENT SUBAREA UNDER POST-DEVELOPMENT CONDITIONS. BY ROUTING RUNOFF FROM THE DEVELOPMENT SUBAREA THROUGH THE 1999 STORMWATER BASIN, THIS PEAK Q IS REDUCED.
- ④ ALLOWABLE PEAK Q IS THE MAXIMUM ALLOWABLE STORMWATER RUNOFF FROM THE DEVELOPMENT SUBAREA UNDER POST-DEVELOPMENT CONDITIONS. IT IS CALCULATED BY SUBTRACTING THE BYPASS AREA PEAK Q FROM THE PRE-DEVELOPED PEAK Q ($23.3 - 12.8 = 10.5$). SINCE THE DEVELOPED PEAK Q (10.7) EXCEEDS THE ALLOWABLE PEAK Q (10.5), THE 1999 STORMWATER BASIN IS NECESSARY TO REDUCE THE DEVELOPED PEAK Q TO ENSURE POST-DEVELOPMENT STORMWATER RUNOFF FROM THE WATERSHED DOES NOT EXCEED THAT OF PRE-DEVELOPMENT CONDITIONS.

Basin Outlet Pipe

1999 Stormwater Basin Outlet Pipe Design

Assuming a 15-inch diameter PVC pipe on a 2.8% slope is used, determine pipe-full capacity (no tailwater conditions) and the maximum allowable tailwater condition.

- 1) Pipe-full capacity is determined using the Darcy-Weisbach Equation and assuming no head or tailwater conditions:

$$S_o = \text{Pipe Slope} = 0.028$$

$$f = \text{Pipe Friction Factor} \cong 0.013$$

$$D = \text{Pipe Diameter} = 15" = 1.25'$$

$$V = \text{Flow Velocity}$$

$$S_o = \frac{fv^2}{D^2g}$$

$$V = \sqrt{\frac{S_o D^2 g}{f}}$$

Since $Q = VA$,

$$Q = \frac{\pi D^2}{4} \sqrt{\frac{S_o D^2 g}{f}} = \sqrt{\frac{\pi^2 g S_o D^5}{8f}} = \sqrt{\frac{\pi^2 (32.2)(0.028)(1.25)^5}{8(0.013)}}$$

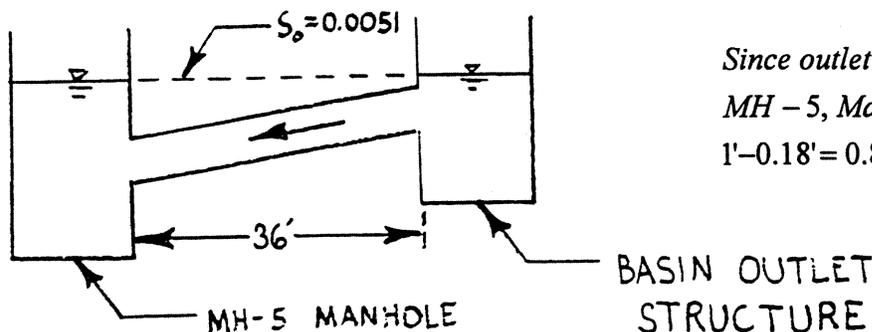

$$Q = 16.2 \text{ cfs} \quad (\text{Pipe - flow capacity with no tailwater or headwater conditions})$$

- 2) Maximum allowable tailwater is determined by solving the Darcy-Weisbach Equation for minimum required slope to convey 6.9cfs (i.e., peak discharge from basin outlet structure):

$$S_o = \frac{8fQ^2}{\pi^2 g D^5} = \frac{8(0.013)(6.9 \text{ cfs})^2}{\pi^2 (32.2)(1.25)^5}$$

$$S_o = 0.0051 = \text{Minimum required slope to convey 6.9cfs}$$

$$(0.0051)(36') = 0.18' = \text{Minimum required water surface drop between outlet and MH - 5}$$

Since outlet pipe drops 1' between outlet and MH - 5, Maximum allowable tailwater = 1' - 0.18' = 0.82'

Perimeter Ditch

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: BMS Date: 05-09-00
TITLE: Engineering Design Calculations Reviewed By: PHB Date: 5/8/00
SUBJECT: OPCA - 1999 Stormwater Basin Perimeter Ditch Design

OBJECTIVE:

Determine required flow capacity and size for the 1999 stormwater basin perimeter drainage ditch based on the estimated peak discharge from the 10-year, 24-hour design storm.

REFERENCES:

1. Technical drawings and figures contained in the Detailed Work Plan for On-Plant Consolidation Areas prepared by Blasland, Bouck & Lee, Inc. (BBL), dated June 1999 (Work Plan).
2. Technical Release 55 "Urban Hydrology for Small Watersheds", Soil Conservation Service, June 1986.
3. Quick TR-55 Urban Hydrology for Small Watersheds Version 5.47 (DOS) computer-based implementation of the Soil Conservation Service's TR-55 methodology, Haestad Methods, Inc..
4. "Open Channel Flow," page 100, Henderson, F.M., 1966.
5. "Stormwater Technical Handbook", MA Department of Environmental Protection, and MA Office of Coastal Zone Management, March 1997.

ASSUMPTIONS:

1. Minimum invert grade of drainage ditch is 1%.
2. Drainage ditch is grass-lined.
3. Minimum freeboard is 6 inches.
4. Curve numbers for drainage ditch subarea:
 - Impervious areas such as roadways = 98
 - Developed consolidation areas (grassland, fair condition, hydrologic soil group C) = 79

METHODOLOGY:

1. Delineate drainage subarea for the drainage ditch (refer to Watershed Area Map).
2. Calculate peak stormwater runoff from the drainage ditch subarea using Quick TR-55.
3. Determine geometry and resulting hydraulic conditions for the drainage ditch.

CALCULATIONS:**1. Peak Discharge:**

The following table provides a summary of the drainage ditch subarea input data and the resulting runoff conditions. Output data for this analysis is included at the end of this section.

1. Technical drawings and figures contained in the Detailed Work Plan for On-Plant Consolidation Areas, prepared by Blasland, Bouck & Lee, Inc. (BBL), June 1999 (Work Plan).

ASSUMPTIONS:

1. Culvert consists of corrugated, smooth-walled HDPE pipe(s) having Manning "n" of approximately 0.011.
2. Minimum invert slope of culvert is 1%.
3. Required culvert capacity is equal to the design capacity of the 1999 perimeter drainage ditch.

METHODOLOGY:

1. Determine required culvert capacity.
2. Determine configuration and resulting hydraulic conditions for the culvert.

CALCULATIONS:**1. Required Culvert Capacity:**

The estimated peak discharge for the perimeter drainage ditch from the 10-year, 24-hour design storm is 4 cfs. Since the culvert conveys stormwater runoff from the same watershed as the perimeter ditch, the required culvert capacity is also 4 cfs. Refer to perimeter drainage ditch design for watershed runoff calculations.

2. Culvert Configuration and Resulting Hydraulic Conditions

Using the Manning equation, determine the minimum pipe diameter necessary to convey estimated peak discharge:

$$Q = \frac{1.49}{n} AR^{2/3} S^{1/2}$$
$$d = \left[\frac{4^{5/3} Qn}{1.49 \pi S^{1/2}} \right]^{3/8},$$

where:

Q = 4 cfs (estimated peak discharge)
n = 0.011 (Manning "n" for HDPE pipe)
S = 0.01 (invert slope of pipe)
d = pipe diameter

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: BMS Date: 05-09-00
TITLE: Engineering Design Calculations Reviewed By: _____ Date: _____
SUBJECT: OPCA - Drainage Culvert Design

$$d = \left[\frac{4^{5/3} (4)(0.011)}{1.49 \pi (0.01)^{1/2}} \right]^{3/8} = 0.98 \text{ ft} = 12 \text{ in}$$

To provide additional capacity during the development of the consolidation areas, use two 12-inch diameter HDPE pipes.

Dear Mr. Torosian

One (1) sample was received for testing on 9/13/99. The sample was identified as follows:

SAMPLE I.D.

AGP COMMENTS

GTX-2

GT

The sample was tested in accordance with the test methods listed below:

ASTM D 3776, "Test Method for Mass per Unit Area (Weight) of Woven Fabric"

ASTM D 3786, "Test Method for Hydraulic Bursting Strength Of Knitted Goods And Nonwoven Fabrics - Diaphragm Strength Tester Method"

ASTM D 4533, "Test Method for Trapezoid Tearing Strength of Geotextiles"

ASTM D 4632, "Test Method for Breaking Load and Elongation of Geotextiles (Grab Method)"

ASTM D 4833, "Test Method for Index Puncture Resistance of Geotextiles, Geomembranes, and Related Products"

All tests were performed at 73° F \pm 3° with a relative humidity of 50% \pm 5%. Conditioning of the samples, before testing, is standard 40 hours at test temperature and relative humidity unless waived by the client.

The sample material was submitted by Geo Testing Express. AGP Laboratories, Inc. has no specific knowledge as to conditioning, origin, sampling procedure, special use of material, or purpose of material. The testing listed herein is based upon accepted industry practice as well as by the test method listed. AGP Laboratories, neither accepts nor makes claim as to final use and purpose of the material. Results presented apply only to the items tested.

Leachate Collection System Pipe Size Calculation

CLIENT: General Electric Company Prepared By: KFP Date: 05-04-00
PROJECT: Pittsfield RD/RA Work Plan -1999 Checked By: RTB Date: 5/31/00
On-Plant Consolidation Areas
SUBJECT: Leachate Collection Pipe Size Calculations

OBJECTIVE:

1. Determine the required size for the leachate collection pipe to convey the leachate generated during the peak leachate production period. Estimated peak leachate flow generated during the peak production period must be equal to or less than the maximum flow capacity of the collection pipe.

REFERENCES:

1. "Detailed Work Plan for On-Plant Consolidation Areas" drawings, prepared by Blasland, Bouck, & Lee, Inc., dated July 1999.
2. Hydraulic Evaluation of Landfill Performance (HELP) Model Version 3.07a. (Phase1a.OUT, Phase1b.OUT, Phase2a.OUT, and Phase2b.OUT).
3. Technical Paper No. 40 (TP-40), Department of Commerce, May 1961 (rev. December 1982).

ASSUMPTIONS:

1. Collection pipe slope is 0.5% minimum (actual slope may be equal to or greater than 0.5%).
2. Inflow to the collection pipe is based on the estimated GDC flow capacity.
3. The collection pipe is perforated, smooth-walled HDPE.

METHODOLOGY:

1. Calculate the estimated peak inflow to the collection pipe from the GDC within the leachate management system assuming a worst case scenario of a combination of the following two conditions:

Condition A.) Approximately 75-percent (3.1 acres) of the consolidation area has been filled to capacity with waste (maximum waste depth of 27-feet) and no components of the final cover system have been installed. Approximately 1.9 acres of the 3.1 acres has been covered with an interim soil cover layer supporting vegetation, while the remaining 1.2 acres has interim cover with no vegetation.

Condition B.) The remaining 25-percent (1.0 acre) of the consolidation area consists of the exposed liner system with the GDC being the uppermost layer. Use the 2-year, 24-hour storm to determine the infiltration rate (from precipitation map). All leachate generated by this event will be collected by the GDC and conveyed to the leachate collection pipe.
2. Calculate the minimum pipe size required based on the estimated peak inflow from the GDC.

CLIENT: General Electric Company Prepared By: KFP Date: 05-04-00
 PROJECT: Pittsfield RD/RA Work Plan -1999 Checked By: _____ Date: _____
On-Plant Consolidation Areas
 SUBJECT: Leachate Collection Pipe Size Calculations

DEFINITIONS:

$Q_A = 1402 \cdot \frac{\text{ft}^3}{\text{day}}$ Peak Inflow for Condition A - Sum of HELP Model output from Phase1a.OUT, Phase1b.OUT, Phase2a.OUT, and Phase2b.OUT

$A_B = 1.0 \cdot \text{acre}$ Approximate total area for Condition B

$q_B = 2.86 \cdot \frac{\text{in}}{\text{day}}$ Peak Infiltration Rate for Condition B (2-year, 24-hour storm event)

$n = 0.011$ Manning's friction coefficient for the collection pipe

$S_{\text{pipe}} = 0.5\%$ Minimum Pipe Slope

CALCULATIONS:

1. Determine the peak inflow (Q_p) into the collection pipe from the GDC Layer.

For Condition "A":

$$Q_A = 0.016 \cdot \frac{\text{ft}^3}{\text{sec}}$$

For Condition "B":

$$Q_B = A_B \cdot q_B \quad Q_B = 0.12 \cdot \frac{\text{ft}^3}{\text{sec}}$$

Total Worst Case Peak Inflow into the Leachate Collection Pipe:

$$Q_{\text{total}} = Q_B - Q_A \quad Q_{\text{total}} = 0.136 \cdot \frac{\text{ft}^3}{\text{sec}}$$

2. Calculate the minimum required collection pipe diameter (D_{min}) size to convey the expected peak flow.

$$D_{\text{min}} = \left(\frac{2.159 \cdot Q_{\text{total}} \cdot n^{\frac{3}{8}}}{S_{\text{pipe}}^{\frac{1}{2}}} \right)^{\frac{3}{8}}$$

$$D_{\text{min}} = 0.315 \text{ ft}$$

$$D_{\text{minr}} = D_{\text{min}} \cdot 12 \cdot \text{in}$$

$$D_{\text{minr}} = 3.8 \cdot \text{in}$$

Use 6-inch diameter pipe

CALCULATION SHEET

Page 3 of 3

Project No.: 20185

CLIENT: General Electric Company Prepared By: KFP Date: 07-28-99
PROJECT: Pittsfield RD/RA Work Plan -1999 Checked By: Date:
On-Plant Consolidation Areas
SUBJECT: Leachate Collection Pipe Size Calculations

CONCLUSIONS:

Use 6-inch diameter perforated HDPE pipe to convey the leachate generated during the peak leachate production period.

CLIENT: General Electric Company Prepared By: KFP Date: 07-28-99
 PROJECT: Pittsfield RD/RA Work Plan -1999 Checked By: _____ Date: _____
On-Plant Consolidation Areas
 SUBJECT: Required Leachate Collection Pipe Wall Thickness Calculations

CALCULATIONS:

1. Determine the FS for Wall Crushing

Calculate the total vertical soil pressure at the top of the pipe (P_t):

$$P_t = \gamma_{wc} \cdot t_c + \gamma_{wf} \cdot t_f \qquad P_t = 31.6 \cdot \frac{\text{lb}}{\text{in}^2}$$

Calculate the actual maximum compressive stress in the pipe (S_A):

$$S_A = \frac{\text{SDR} - 1}{2} \cdot P_t \qquad S_A = 252.9 \cdot \frac{\text{lb}}{\text{in}^2}$$

According to Reference 2, pg. 37, the actual compressive yield strength of Driscopipe is:

$$S_{act} = 1500 \cdot \frac{\text{lb}}{\text{in}^2} \qquad (\text{Reference 2, pg. 37})$$

Calculate the factor of safety (FS):

$$FS_{wc} = \frac{S_{act}}{S_A} \qquad FS_{wc} = 5.93 \qquad \Leftarrow \text{OK}$$

2. Calculate the adequacy of the pipe with respect to ring deflection

Due to the "bridging" effect of the stone used to backfill the collection pipe, the vertical elastic strain (i.e. - ring deflection) experienced by the pipe is equal to the vertical elastic strain experienced by the granular fill due to the overburden pressure of the consolidation material.

Calculate the granular fill vertical elastic strain (ϵ):

$$\epsilon = \frac{P_t}{E'} \qquad \text{Where: } E' = 1000 \cdot \frac{\text{lb}}{\text{in}^2} \qquad (\text{Reference 2, pg 36; assuming Soil Type I: crushed stone, loosely placed})$$

$$\epsilon = 3.2\%$$

Allowable ring deflection (ϵ_{rd}) for SDR 17 pipe is:

$$\epsilon_{rd} = 4.2\% \qquad (\text{Reference 2, Chart 27, pg. 38})$$

Therefore:

$$\epsilon < \epsilon_{rd}$$

$$3.2\% < 4.2\% \qquad \Leftarrow \text{OK}$$

CLIENT: General Electric Company Prepared By: KFP Date: 07-28-99
 PROJECT: Pittsfield RD/RA Work Plan -1999 Checked By: _____ Date: _____
On-Plant Consolidation Areas
 SUBJECT: Required Leachate Collection Pipe Wall Thickness Calculations

2. Determine the FS for Wall Buckling

Determine the pipe's modulus of elasticity (E) according to Chart 25 of Reference 2, page 37

$$E = 26500 \cdot \frac{\text{lb}}{\text{in}^2} \quad (\text{With } S_A = 252.9 \cdot \frac{\text{lb}}{\text{in}^2} ; \text{ and a Design Life} = 50 \text{ years})$$

Calculate the pipe's hydrostatic, critical-collapse differential pressure (P_c):

$$P_c = \frac{2.32 \cdot E}{\text{SDR}^3} \quad P_c = 12.5 \cdot \frac{\text{lb}}{\text{in}^2}$$

Calculate the critical buckling soil pressure at the top of the pipe (P_{cb}):

$$P_{cb} = 0.8 \cdot (E \cdot P_c)^{\frac{1}{2}} \quad P_{cb} = 89.5 \cdot \frac{\text{lb}}{\text{in}^2}$$

Calculate the factor of safety with respect to wall buckling:

$$\text{FS}_{wb} = \frac{P_{cb}}{P_t} \quad \text{FS}_{wb} = 2.8$$

The recommended FS for wall buckling is:

$$\text{FS}_{wbrec} = 2.0 \quad (\text{Reference 2, pg. 38})$$

Therefore:

$$\text{FS}_{wb} > \text{FS}_{wbrec}$$

$$2.8 > 2.0 \quad \leq \text{OK}$$

CONCLUSIONS:

An SDR 17, 6-inch diameter perforated HDPE pipe meets the manufacturer's recommended minimum design requirements and is therefore selected for the leachate collection pipe wall thickness.

If flow is likely to be stopped, the designer may want to provide a means to drain the pipeline partially or completely. If, for some unforeseen reason, the Driscopipe pipeline should plug and freeze, the pipeline will not be damaged. The frozen fluid may swell the diameter of the pipe but it will return to nominal size as the fluid thaws. Due to the nature of polyethylene pipe, a flame (such as a propane or acetylene torch) cannot be used to thaw a frozen section of pipe. Other methods must be used.

The toughness and excellent abrasion resistance of Driscopipe will take the abuse of movement across sand and soil without detrimental effects on its strength or service life. However, in rocky areas, sharp rocks which could cut the pipe should be removed and may be replaced with a bed of sand or soil.

Lateral Deflection Due to Thermal Movement in Overland Pipelines.

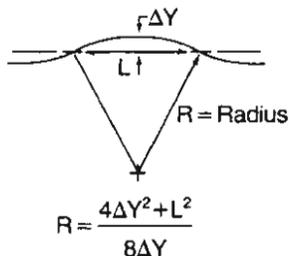

The following formulae will allow the designer to calculate lateral deflection of the pipeline and anchor point spacing.

$$\Delta Y = L \sqrt{.50\alpha\Delta T} \quad (1)$$

$$L = \frac{\Delta Y}{\sqrt{.50\alpha\Delta T}} \quad (2)$$

$$L = \frac{D\sqrt{96\alpha\Delta T}}{\epsilon} \quad (3)$$

- Where: ΔY = Lateral deflection (inches)
 L = Length of pipe between anchors (inches)
 α = Coefficient of thermal expansion (in/in/°F)
 ΔT = Change in temperature (°F)
 ϵ = Strain (inches/inch)
 D = Pipe outside dia. (inches)

Examination of equation (1) or (2) shows that for any given set of thermal conditions an increase in ΔY will increase L and vice versa. Increasing ΔY and L to the maximum will reduce the number of anchor points needed but may increase wear on the pipe from movement and may increase the possibility of kinking the line if lateral movement does not occur uniformly. One practical approach to design is to calculate L using formula (3) for strain (ϵ) in the pipe wall equal to 1% and (ϵ) equal to 5%. The L value at 5% strain will give the shortest distance between anchor points and should be considered maximum for strain (ϵ) and minimum spacing for L . The spacing for L should be as large as possible considering other installation location factors, such as available right-of-way, slope of the ground, etc. Higher values for L mean less strain (ϵ) and fewer anchor points and, consequently, lower costs, generally.

Type 3: Buried Pipelines

Introduction: When pipelines are buried, they are subjected to external loads. The effect of external pressure on flexible Driscopipe is more complex than the effect of internal pressure only. For design purposes, a distinction is usually made between rigid and flexible pipes. A rigid pipeline (such as concrete) is considered to be the total structure and must be designed to sustain all external loads as well as internal pressure. But, Driscopipe is a flexible pipe and is considered to be only one component of the "pipe-soil" system, as described more fully on page 35.

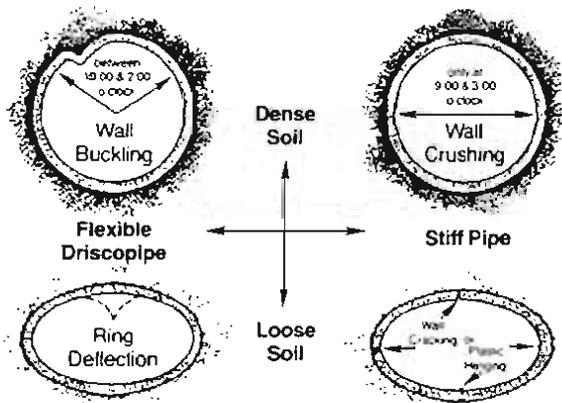

Thus, in a buried situation, the SDR of the pipe and the strength of the soil envelope must be specified in order to keep the three burial design parameters (wall crushing, wall buckling and ring deflection) within acceptable limits. The pipe and soil envelope become one system. The mutual interaction and strength contribution of the pipe to the soil and the soil to the pipe result in a highly successful integral structure. Correct design centers around two points: a) matching the proper wall thickness to the external soil pressure and b) the analysis of how Driscopipe and the soil surrounding the pipe accept the backfill earthloading and transfer it to the undisturbed walls of the ditch or trench such that the pipeline will deflect slightly into static equilibrium with the soil.

Design Considerations: Driscopipe performs effectively when buried because of its ability to deflect in the interacting pipe-soil system. The pipe actually gains strength from the surrounding soil and can support additional soil loads. The soil envelope surrounding the pipe will compress or deflect slightly under the additional loads of the dry weight of backfill above the pipe, the weight of the water table saturating the soil, the weight of nearby buildings or static structures, the weight of off-the-road trucks and tractors, railroad freight trains or any combination of all these loads. In a flexible "pipe-soil" system, the pipe deflection is the same as the soil deflection under the load of the secondary backfill and any surface loads.

When the pipeline is laid in the trench, the soil envelope is shoveled, washed, flushed or dumped into place, in layers, to an elevation above the top of the pipe. It is usually compacted to a specified Proctor density by mechanical or hydraulic means. As additional layers of soil are backfilled into the trench, the weight of the soil over the primary, compacted backfill is increased. This increased weight slightly compresses (strains downwards) the soil envelope. The amount of soil compression is related to the strength of the soil at a given density and to the intensity of the vertical soil pressure. Since the soil is not an elastic material, this compression or strain of the soil envelope by the final backfill is permanent. As the soil envelope is compressed (strained), it becomes further compacted. In its denser state, the soil develops increased resistance to the vertical soil pressure until it reaches static equilibrium without further compression or strain. This is the reaction of the compacted soil envelope.

Typical Performance Limits of Buried Pipes Due to External Soil Pressure

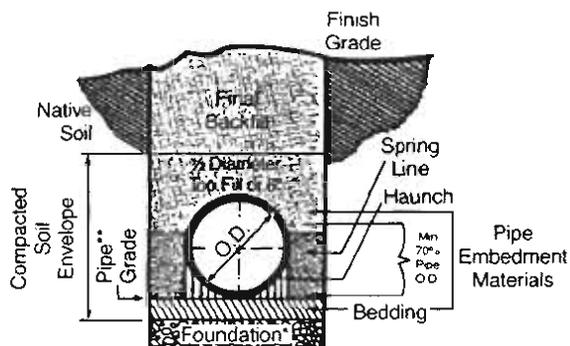

Through mathematical computations presented later, the ring deflection of Driscopipe can be calculated based upon the known properties of the pipe and the measured compressibility of the soil envelopes. As the pipe deflects with the soil, it forms a very slight ellipse by decreasing in the vertical diameter an amount ΔY and by increasing in the horizontal diameter an almost equal (but slightly less) amount ΔX . The horizontal diametrical increase is beneficial because it further compacts the sidefill soil and thus develops lateral support in a fashion similar to the way soil abutments offer support to a masonry arch bridge. The compacted soil actually becomes a masonry arch even though the soil is a low grade masonry using soil particles for bricks. The vertical decrease in diameter is beneficial because it relieves the pipe of vertical soil pressure concentrations and thus forces the soil to support the major share of the vertical load by arching action over the pipe.

Compressibility of the soil envelope is measured by the Soil Modulus, E' , which is the ratio of soil pressure (stress) to soil deflection (strain) at a given soil compaction density, as shown in Chart 26. The degree of compaction of the soil envelope can be determined from a family of curves developed from laboratory tests. Chart 26 is typical of such curves and provides a general guide if laboratory data are not available to plot a family of curves for a specific soil type.

Deformation of buried flexible pipe becomes critical only when the pipe reaches that point of ring deflection beyond which it can no longer resist any increase in soil loading. By limiting ring deflection through proper soil compaction, the loading over a pipe is distributed through the soil and across the soil arch around the pipe. Thus the pipeline maintains its circular cross-section in stable soils and is protected against long term collapse.

Trench Construction and Terminology

* In suitable soils the construction of a bedding and/or a foundation may not be required.

** Gravity flow Driscopipe sewers may be accurately laid to grade using laser-beam scoping.

Simplified Burial Design: A conservative estimate of the ability of Driscopipe pipelines to perform in a buried environment is found in Chart 24. It is based on a minimum 2:1 safety factor and 50 year design service life. A detailed burial design starts on page 37. The detailed design should be used for critical or marginal applications or whenever a more precise solution is desired.

Detailed Burial Design:
Design by Wall Crushing: Wall crushing would theoretically occur when the stress in a pipe wall, due to the external vertical pressure, exceeded the long-term compressive strength of the pipe material. To ensure that the Driscopipe wall is strong enough to endure the external pressure the following check should be made:

$$S_A = \frac{(SDR - 1)}{2} P_T$$

Values of E'

Based on Soil Type (ASTM D2321) and Degree of Compaction

Soil Type of Initial Backfill Embedment Material	Description	E' (psi) for Degree of Compaction (Proctor Density, %)			
		Loose	Slight (70-85%)	Moderate (85-95%)	High (95%)
I	Manufactured angular, granular materials (crushed stone or rock, broken coral, cinders, etc.)	1,000	3,000	3,000	3,000
II	Coarse grained soils with little or no fines	N.R.	1,000	2,000	3,000
III	Coarse grained soils with fines	N.R.	N.R.	1,000	2,000
IV	Fine-grained soils	N.R.	N.R.	N.R.	N.R.
V	Organic soils (peat, muck, clay, etc.)	N.R.	N.R.	N.R.	N.R.

N.R. = Not Recommended for use by ASTM D2321 for pipe wall support

Chart 24

7.3	26	52	79	18	36	55	1.8	0.9	0.6

*assumes no external loads

Where: S_A = Actual compressive stress, psi
 SDR = Standard Dimension Ratio
 P_T = External Pressure, psi

Safety Factor = $1500 \text{ psi} \div S_A$ where 1500 psi is the Compressive Yield Strength of Driscopipe.

Design by Wall Buckling: Local wall buckling is a longitudinal wrinkling of the pipe wall. Tests of non-pressurized Driscopipe show that buckling and collapse do not occur when the soil envelope is in full contact with the pipe and is compacted to a dense state. However, it can be forced to occur over the long term in non-pressurized pipe if the total external soil pressure, P_T , is allowed to exceed the pipe-soil system's critical buckling pressure, P_{cb} . If $P_T > P_{cb}$, gradual collapse may occur over the long term. A calculated, conservative value for the critical buckling pressure may be obtained by the following approximate formula. All pipe diameters with the same SDR in the same burial situation have the same critical collapse and critical buckling endurance

$$P_{cb} = 0.8 \sqrt{E' \times P_c}$$

Where:

P_T = Total vertical soil pressure at the top of the pipe, psi

P_{cb} = Critical buckling soil pressure at the top of the pipe, psi

E' = Soil modulus in psi calculated as the ratio of the vertical soil pressure to vertical soil strain at a specified density

P_c = Hydrostatic, critical-collapse differential pressure, psi

$$P_c = \frac{2E (t/D)^3 (D_{MIN}/D_{MAX})^3}{(1 - \mu^2)}$$

$$P_c = \frac{2.32 E}{(SDR)^3}$$

Where: $(D_{MIN}/D_{MAX}) = .95$

μ = Poisson's Ratio

$\mu = .45$ for Driscopipe

E = stress and time dependent tensile modulus of elasticity, psi

In a direct burial pressurized pipeline, the internal pressure is usually great enough to exceed the external critical-buckling soil pressure. When a pressurized line is to be shut down for a period, wall buckling should be examined.

Design by Wall Buckling Guidelines:

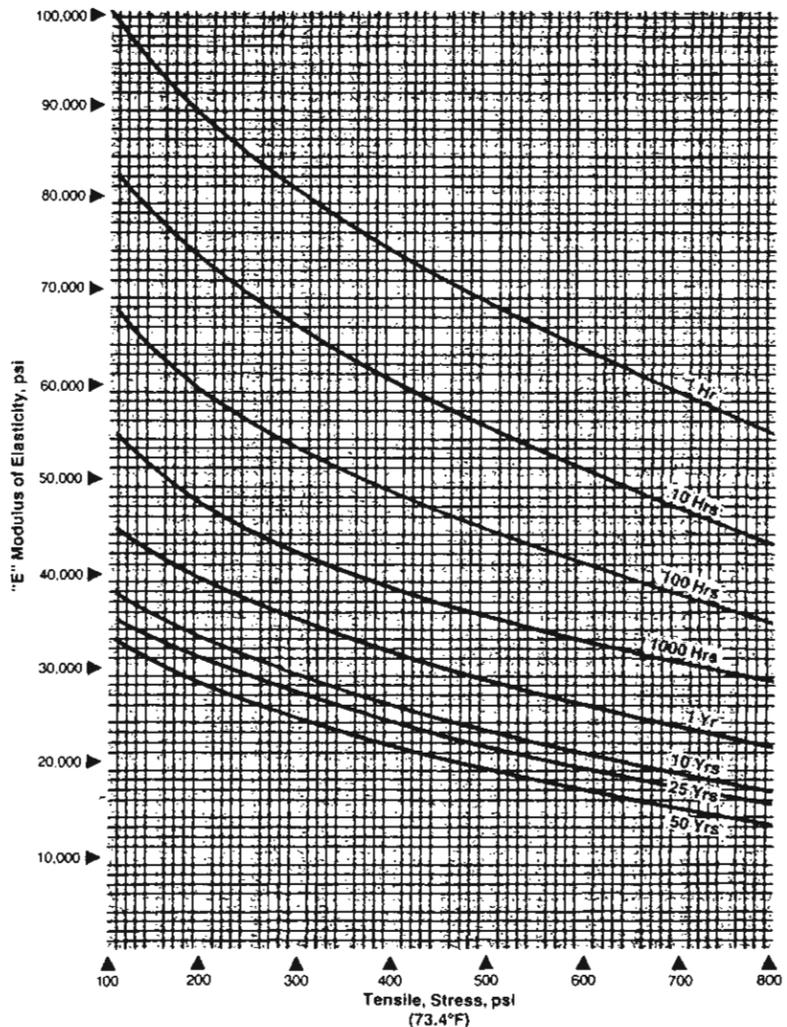

Although wall buckling is seldom the limiting factor in the design of a Driscopipe system, a check of non-pressurized pipelines can be made according to the following steps to insure $P_T < P_{cb}$.

1. Calculate or estimate the total soil pressure, P_T , at the top of the pipe.
2. Calculate the stress " S_A " in the pipe wall according to the formula:

$$S_A = \frac{(SDR - 1) P_T}{2}$$

3. Based upon the stress " S_A " and the estimated time duration of non-pressurization, use Chart 25 to find the value of the pipe's modulus of elasticity, E , in psi.

Chart 25
Time Dependent Modulus of Elasticity for Polyethylene Pipe vs. Stress Intensity (73.4°F)

NOTE: The short term modulus of elasticity of Driscopipe per ASTM D 638 is approximately 100,000 psi. Due to the cold flow (creep) characteristic of the pipe material, this modulus is dependent upon the stress intensity and the time duration of the applied stress.

- Based upon the pipe SDR and the value of the polyethylene modulus of elasticity, E, calculate the pipe's hydrostatic, critical-collapse differential pressure, P_c :

$$P_c = \frac{2.32(E)}{(SDR)^3}$$

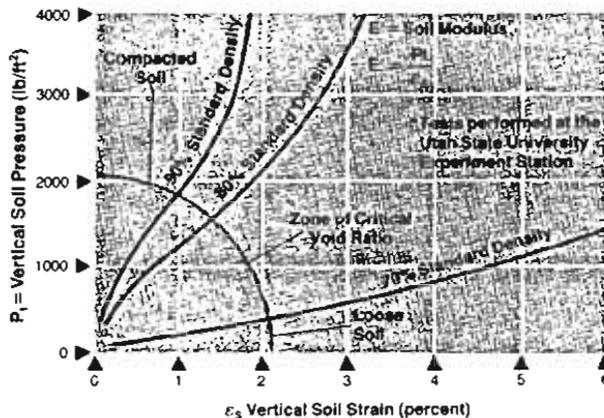

- Calculate the soil modulus, E' , by plotting the total external soil pressure, P_1 , against a specified soil density to derive the soil strain as shown in the example problem on Chart 26.
- Calculate the critical buckling pressure at the top of the pipe by the formula:

$$P_{cb} = 0.8 \sqrt{E' \times P_c}$$

- Calculate the Safety Factor: $S.F. = P_{cb} \div P_1$
In burial applications, a safety factor of 1.0 may be considered a minimum because of the margin of safety provided by the arching action of the soil. However, Driscopipe endorses using a more conservative value approaching or exceeding a 2.0 safety factor.

- The above procedures could be reversed to derive the minimum pipe SDR required for a given soil pressure and an estimated soil density. However, this procedure should permit the engineer to optimize the system design quickly by examining several combinations.

Chart 26
Plot of Vertical Stress-Strain Data for Typical Trench Backfill (Except Clay) from Actual Tests*

EXAMPLE

Find: E' @ 2000 PSF and 80% Density
Formula: $E' = P_1 / \epsilon_s$
Calculations: $E' = 2000 \text{ PSF} / .018 = 111111 \text{ PSF} = 771 \text{ psi}$

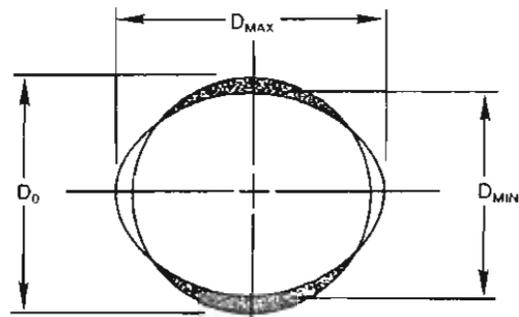

Note: The curves shown on this chart are sample curves for a granular soil. If other types of soil are used for backfill, such as clay or clay loam, curves should be developed from laboratory test data for the material used. Soil pressures greater than 4000 psf may be examined by extrapolating the slope of the curve or by generating curves by testing at those higher soil pressures. Probable error of curves is about half the distance between adjacent lines.

Design by Ring Deflection Ring deflection is defined as the ratio of the vertical change in diameter to the original diameter. It is often expressed as a percentage. Ring deflection for buried Driscopipe is conservatively the same as (no more than) the vertical compression of the soil envelope around the pipe. Design by ring deflection matches the ability of Driscopipe to accommodate, without structural distress, the vertical compression of the soil enveloping the buried pipeline. *Design by ring deflection comprises a calculation of vertical soil strain to ensure it will be less than the allowable ring deflection of the pipe.* See Chart 27. The tabulation shows that with lower values of SDR, the allowable deflection is less. For installations which require this thicker wall to resist the external soil pressure, actual ring deflection can easily be limited to the tabular values by proper compaction of the backfill around the pipe. The recommended allowable deflection for the various SDRs are:

Chart 27

SDR	Allowable Ring Deflection
32.5	8.1%
26.0	6.5%

The allowable ring deflection of polyethylene pipe is a function of the allowable tangential strain in the outer surface of the pipe wall. A conservative limit of 1-1½% tangential strain in the outer surface of the pipe wall due to vertical deflection of the pipe "ring" by soil compression can be understood by comparing two pipes of the same diameter but different wall thickness.

$$\% \text{ Ring Deflection} = \left(1 - \frac{D_{MIN}}{D_0} \right) \times 100\%$$

NOTE: 5% deflection decreases flow-area by ¼%. 10% deflection decreases flow-area by 1%.

Assume each of the pipes is equally deflected under loads required to achieve that result. The tangential surface strain developed in the thickwall pipe is much greater than the surface strain in the thinwall pipe. The tangential strain varies directly as the wall thickness (i.e.: distance from the neutral axis) and is proportional to the amount of ring deflection. For a given ring deflection, the thicker the wall, the higher the strain.

Alternately, assume that each of the pipes is subjected to loads such that the tangential surface strain in the pipe's wall surface is equal for both pipes. For equal surface strain, the degree of vertical deflection of the pipe ring is different for the two pipes. Under these circumstances, the degree of deflection would be less for the thickwall pipe and greater for the thinwall pipe.

The percentage ring deflection based upon strain for a given SDR pipe can be calculated as follows:

$$\frac{\Delta Y}{D} = (0.25) (\epsilon) \left(\frac{D}{t}\right)$$

$$\frac{\Delta Y}{D} = (0.25) (\epsilon) (\text{SDR})$$

$$\frac{\Delta Y}{D} = (.0025) (\text{SDR})$$

Where: ϵ = Tangential strain in the surface of the pipe ring due to deflection (conservatively 0.01 for Driscopipe)
 D = Pipe OD, inches
 t = Pipe wall thickness, inches
 SDR = Standard Dimension Ratio, D/t
 ΔY = Vertical deflection, inches

Driscopipe recognizes a tangential surface strain value of 0.01 due to ring deflection as a conservative yet responsible design parameter. This value is based upon the following:

- Most of the deflection of a flexible pipe occurs within a few hours or a few days after final backfilling and increases very little thereafter. This results in the development of the soil arch over the pipe which relieves the pipe of much of the vertical soil load by the arching action of the soil envelope and by the development of soil restraint at the sides of the pipe.

- With an allowable long term stress of 800 psi and a time of approximately four days (100 hours) to reach the maximum allowable ring deflection, the tangential strain would be 2% to 2½% (See Chart 25 for time and load dependent modulus of elasticity to calculate: strain = stress ÷ modulus.) Therefore, the use of 800 psi incorporates an additional margin of safety of over 2.0.
- An allowable strain value of 0.01 will allow for reasonable additional deflection due to disturbance of the backfill by earthquake, fluctuations of the water table, etc.
- An allowable design strain value of 0.01 allows for the normal deviation of temperature encountered during installation.

In summary, a soil density can be specified for the bedding and initial backfill so that the vertical strain of the sidefill soil under the total soil pressure, P_v , at the top of the pipe will be no greater than the maximum allowable ring deflection for a given SDR pipe.

Test Performance of Direct Burial Driscopipe: The density of the bedding and soil envelope determines the performance capability of the pipe-soil system with regard to ring deflection. Tests conducted on Driscopipe at Utah State University by Dr. Reynold K. Watkins show that Driscopipe will not buckle under ordinary conditions if the soil envelope is compacted and is in full contact with the pipe. A virtual fail-safe installation can be assured if soil density is generally over 85% of Standard Proctor (AASHTO T-99) Density. With the backfill compacted to 90% of standard density, the depth of laying for Driscopipe is almost unlimited. However, in the thinner wall series, due to the flexibility of the pipe, it is difficult to achieve the desired high soil density without buckling of the pipe cross-section, particularly when using backfill material other than sand or gravel.

Soil densities less than 90% are certainly adequate if depth of soil cover is in the range of most installations. Compaction to 75% standard density is relatively easy to achieve even in poor soils. This would cover a large percentage of all installations. However, 85% Standard Proctor Density (AASHTO T-99) should be considered a conservative minimum.

GDC Minimum Required Transmissivity

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: KFP Date: 05-04-00
TITLE: Engineering Design Calculations Reviewed By: PTB Date: 5/9/00
SUBJECT: OPCA - Geosynthetic Drainage Composite Minimum Required Transmissivity

OBJECTIVE:

Determine the minimum required flow capacity (transmissivity) of the geosynthetic drainage composite (GDC) within the base liner system under anticipated final conditions.

REFERENCES:

1. "Design of Waste Containment Liner and Final Closure Systems," ASCE Seminar Manual, 1998.
2. Hydraulic Evaluation of Landfill Performance (HELP) Model Version 3.07a - (Output File = BASE3.OUT).
3. "Detailed Work Plan for On-Plant Consolidation Areas," drawings, Blasland, Bouck & Lee, Inc., July 1999.
4. "An Introduction to Geotechnical Engineering," Holtz, R.D., page 105, 1981 (included).

ASSUMPTIONS:

1. Base liner GDC must be capable of handling stormwater infiltration for the following condition:
The first lift of consolidation material (uniform 24 inch thick) has been placed within a 1-acre cell of the Building 71 Consolidation Area.
2. Longest slope length for the base liner GDC is 200 feet at 2%.
3. Soil and climatological parameters derived from the HELP model for Plainfield, Massachusetts.
4. Maximum allowable head above the FML in the base liner system is 12 inches.
5. Normal stress to be utilized during laboratory testing is based on the full design thickness of 29 feet (including waste and final cover thickness).
6. The unit weight of the consolidation and final cover materials above the GDC is 157 lb/ft³ (from reference 4).
7. 0% of stormwater runoff is allowed from cell area.

METHODOLOGY:

1. For the conditions stated above, perform an iterative HELP model analysis varying the GDC layer saturated hydraulic conductivity to determine the minimum transmissivity that results in a 12 inch head above the base liner system.

CALCULATIONS:

1. Minimum required transmissivity for the GDC layer:

From the attached HELP model, the minimum hydraulic conductivity that results in a 12 inch head above the base liner system is 30 cm/s.

Equivalent transmissivity is:

CLIENT: General Electric Company PROJECT: GE Pittsfield, MA Prepared By: KFP Date: 05-04-00
 TITLE: Engineering Design Calculations Reviewed By: _____ Date: _____
 SUBJECT: OPCA - Geosynthetic Drainage Composite Minimum Required Transmissivity

$$\frac{30\text{cm/s}}{\left(\frac{100\text{cm}}{1\text{m}}\right)^2 \left(\frac{1}{0.20\text{in}}\right) \left(\frac{1\text{in}}{2.54\text{cm}}\right)} = 1.5 \times 10^{-3} \frac{\text{m}^2}{\text{s}}$$

Determine maximum normal stress, σ_N , and hydraulic gradient, I, associated with the final OPCA condition:

A. Maximum normal stress, σ_N :

$$\sigma_N = \gamma t_{\text{waste}}$$

where:

$\gamma = 157 \text{ lb/ft}^3$ (assumed unit weight of material above GDC)

$t_{\text{waste}} = 29 \text{ ft}$ (thickness of material above GDC)

$$\sigma_N = (157 \text{ lb/ft}^3)(29 \text{ ft}) = 4553 \text{ lb/ft}^2$$

B. Hydraulic gradient, I:

$$I = \frac{h_{\text{max}} + B \sin \theta_b}{\frac{B}{\cos \theta_b}}$$

where:

$h_{\text{max}} = 1 \text{ ft}$ (maximum allowable head)

$B = 61.8 \text{ ft}$ (distance from leachate collection pipe to location of maximum head)

$\theta_b = 1.1^\circ$ (base liner slope angle)

$$I = \frac{1 + 61.8 \sin(1.1)}{\frac{61.8}{\cos(1.1)}} = 0.035$$

CONCLUSIONS:

The required flow capacity (transmissivity) of the geosynthetic drainage composite (GDC) within the base liner system must be at least $1.5 \times 10^{-3} \text{ m}^2/\text{s}$ under the anticipated final OPCA conditions.

RE: Client Job - GTX-2506 Retest of Geocomposite from ETI
 AGP Project Number: GTX 3361.005

Dear Mr. Torosian:

One (1) sample was received for testing on 9/20/99. The sample was identified as follows:

SAMPLE I.D.

GCMP

AGP COMMENTS

GC

The sample was tested in accordance with the test methods listed below:

ASTM D 4716, "Test Method for Constant Head Hydraulic Transmissivity (In-Plane Flow) Of Geotextiles And Geotextile Related Products"

All tests were performed at $73^{\circ}F \pm 3^{\circ}$ with a relative humidity of $50\% \pm 5$. Conditioning of the samples, before testing, is standard 40 hours at test temperature and relative humidity unless waived by the client.

The sample material was submitted by Blasland Bouch & Lee, Inc. AGP Laboratories, Inc. has no specific knowledge as to conditioning, origin, sampling procedure, special use of material, or purpose of material. The testing listed herein is based upon accepted industry practice as well as by the test method listed. AGP Laboratories, neither accepts nor makes claim as to final use and purpose of the material. Results presented apply only to the items tested.

treatments and other lamination processes as thickness of the nonwoven geotextile decreases. Therefore, all nonwoven geotextile used in the production of bonded geocomposites was specified to be at least 10 oz/sy for this project.

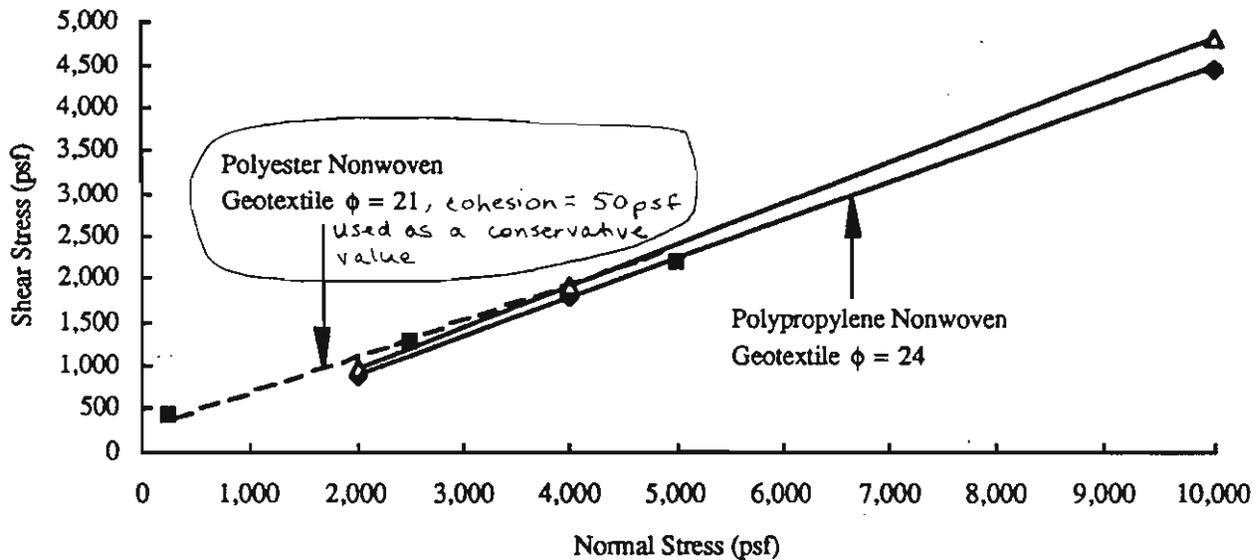

Figure 8. Results of Direct Shear Tests

Effect of Large Loads on Interface Friction: The maximum overburden stresses from overlying waste in the 1.7 hectare area was anticipated to be about 480 kiloPascals (kPa) [10,000 pounds per square foot (psf)]. Prior to this design, direct shear testing on a bonded geocomposite/textured geomembrane interface was typically performed at much lower normal stresses. For this design it was important to evaluate what effect, if any, large normal stresses would have on interface friction. As such, direct shear testing was conducted at 10, 95, 190, 240, and 480 kPa (250, 2,000, 4,000, 5,000, and 10,000 psf) on both continuous filament needlepunched polypropylene and polyester bonded geocomposites.

Test results from this direct shear testing program are provided in Figure 8. Referring to this figure, it is seen that at the higher normal stresses there was essentially no decrease in the slope of the intercept line. This result suggested that the interface friction angle was relatively constant at higher normal stresses, compared to lower normal stresses. This result was somewhat unexpected, since it was assumed that the higher normal stresses would contribute to elastic deformation of the textured surface, with corresponding decrease in interface friction. However, this assumption was not supported by the limited laboratory direct shear test data shown in Figure 8. Even if the results had shown slight differences in interface friction as a function of normal stress, attempting to account for these small differences in the analysis would have been difficult for a 1.7 hectare landfill area, let alone a much larger landfill area.

Effect of Long-Term Loading on Interface Friction: Intuitively, the textured surface on the geomembrane should become slightly smoother with time. This assumption is based on the

HDPE/Underlying Soil Interface Slippage Calculation

Infinite Slope Analysis for Textured HDPE/Underlying Soil Interface

Reference:

1. Bhatia, S.K. and G. Katsuri. "A Report on Comparison of PVC and HDPE Geomembrane (Interface Friction Performance)." for PVC Geomembrane Institute. Dept. Of Civil and Environmental Engineering Syracuse University.

Assumptions:

1. Underlying soil is sand.
2. Interface friction angle, $\phi=29$ degrees (Bhatia, S.K. and G. Katsuri)
3. 3H:1V slope, $\beta=18.4$ degrees

Calculation:

$$FS = \frac{\tan\phi}{\tan\beta}$$

$$FS = \frac{\tan(29)}{\tan(18.4)} = 1.7$$

The factor of safety for a 3H:1V slope with a textured HDPE liner and sand interface is approximately 1.7.

Slope Stability Calculations

Sand/Nonwoven Needlepunched Geotextile (GDC) Interface

Reference:

Koerner, R.M. *Designing with Geosynthetics*. Upper Saddle River, New Jersey: Prentice Hall, 1998.

Landslides Investigation and Mitigation Special Report 247. Turner, A.K. and R. L. Schuster Ed. Washington, D.C.: Academy Press, 1996.

Assumptions:

1. Interface friction angle, $\phi=30$ degrees (Koerner, 1998 see attached)
2. 3H:1V slope, $\beta=18.4$ degrees
3. 14 inches of head
4. 2 feet of sand cover

Calculation (Landslides, 1996 - see attached):

$$FS=A \frac{\tan\phi}{\tan\beta}$$

Estimating the A parameter:

$$r_u = \frac{u}{\gamma H} = \frac{62.4pcf * (\frac{14inches}{12inches})}{125pcf * 2ft} = 0.29$$

$$b = \cot\beta = 3.0$$

from Figure 13-8 (see attached), a r_u value of 0.29 and a b value of 3.0 correspond to an A parameter of 0.69.

$$FS = \frac{0.69 * \tan 30}{\tan 18.4} = 1.2$$

The factor of safety for a sand/nonwoven needlepunched geotextile interface on a 3H:1V slope with 14 inches of head is approximately 1.2

*Efficiency values (in parentheses) are based on the relationship $E = (\tan \delta)/(\tan \phi)$.

Source: After Martin et al. [17]

The frictional behavior of geomembranes placed on clay soils is of considerable importance for composite liners containing solid or liquid wastes. The current requirements are for the clay to have a hydraulic conductivity equal to or less than 1×10^{-7} cm/s and for the geomembrane to be placed directly upon the clay. While an indication of the shear strength parameters has been investigated (e.g., [18]), the data are so sensitive to the variables discussed previously that site-specific and material-specific tests should always be performed. *In such cases, literature values should never be used for final design purposes.*

Much of the direct shear literature data is for peak shear strengths (e.g., the data in Table 5.7). Stark and Poeppel [19] have challenged this situation by testing various geosynthetic interfaces in a ring-shear device. In using such a device, significantly larger

INVESTIGATION AND MITIGATION

SPECIAL REPORT 247

TRANSPORTATION RESEARCH BOARD
National Research Council

The background of the cover features a detailed technical cross-section of a landslide. The drawing shows a slope with various layers and failure surfaces. Key labels include 'M' and 'F' marking specific points or features within the slope. Handwritten annotations in French, such as 'avant le glissement' (before the slide) and 'après le glissement' (after the slide), describe different stages of the event. The drawing is overlaid with a grid and includes various dimension lines and scale markers.

5.4 Infinite Slope Analyses

Conditions are sometimes encountered in which a layer of firm soil or rock lies parallel to the surface of the slope at shallow depth. In such conditions the slip surface is constrained to parallel the slope, as shown in Figure 13-8. When such slip surfaces are long compared with their depth, they can be approximated accurately by infinite slope analyses. Such analyses ignore the driving force at the upper end of the slide mass and the resisting force at the lower end. The resisting force is ordinarily greater, and infinite slope analyses are therefore somewhat conservative.

The factor of safety for infinite slope analyses can be expressed as

$$F = A \frac{\tan \phi'}{\tan \beta} + B \frac{c'}{\gamma H} \tag{13.15}$$

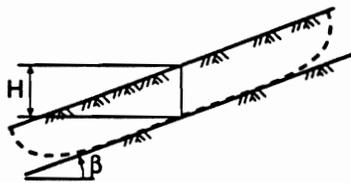

where

A, B = dimensionless stability coefficients given in Figure 13-8,

ϕ' , c' = effective stress strength parameters for slip surface,

β = slope angle,

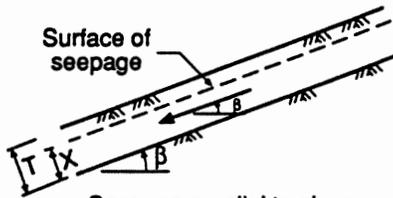

γ = unit weight of sliding mass (force per length cubed), and

- γ = total unit weight of soil
 - γ_w = unit weight of water
 - c' = cohesion intercept
 - ϕ' = friction angle
 - r_u = pore pressure ratio = $\frac{u}{\gamma H}$
 - u = pore pressure at depth H
- } Effective Stress

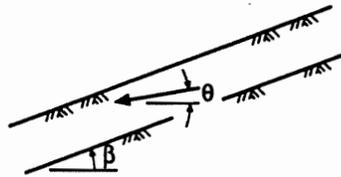

Steps:

- ① Determine r_u from measured pore pressures or formulas at right
- ② Determine A and B from charts below
- ③ Calculate $F = A \frac{\tan \phi'}{\tan \beta} + B \frac{c'}{\gamma H}$

Seepage parallel to slope

$$r_u = \frac{X}{T} \frac{\gamma_w}{\gamma} \cos^2 \beta$$

Seepage emerging from slope

$$r_u = \frac{\gamma_w}{\gamma} \frac{1}{1 + \tan \beta \tan \phi}$$

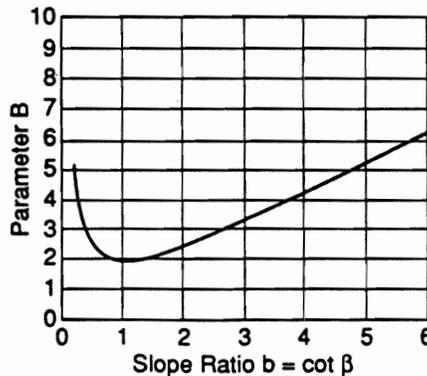

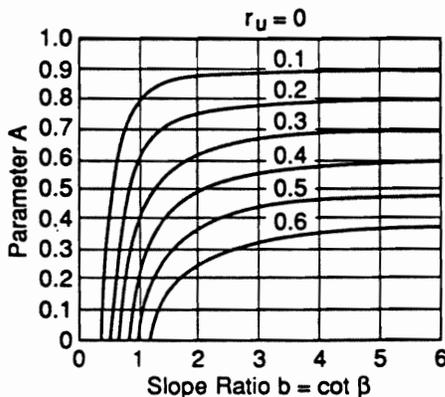

FIGURE 13-8 Stability charts for infinite slopes (modified from Duncan et al. 1987).

Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G029**

DATE: May 18, 2000

SAMPLE RECEIPT OBSERVATIONS:

The samples were received June 15, 1999 at 9:15 via FedEx in good condition. The receipt temperature was 5°C. The dioxin analysis was sub-contracted to Columbia Analytical Services with the approval of BBL. There was no volatiles analysis performed per the client.

CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G029

DATE: May 18, 2000

SEMIVOLATILES REPORT:

The samples were analyzed for GE App. IX + 3 Semivolatiles in accordance to the guidelines of method SW8270C.

The tunes, initial calibration and continuing calibration verifications met acceptance criteria.

The internal standard areas were within quality control criteria.

The surrogate standard percent recoveries were within quality control criteria.

The laboratory control sample met acceptance criteria.

The method blank was free of interference.

The PRRL's (reporting limits) are adjusted for percent solids and extraction volumes as applicable.

The sampling to extraction holding time of fourteen days and extraction to analysis holding time of forty days was met for all samples.

**CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G029**

DATE: May 18, 2000

PCB REPORT:

The samples were analyzed according to the guidelines of Method 8082.

The PCB responses were quantitated by the Aroclor multi-component analysis, using at a minimum three unique peaks of the pattern.

All initial calibration and continuing calibration verifications met acceptance criteria. The 5 pt. initial calibration consists of PCB 1016, 1260 and 1254/Surrogates. Single point pattern recognition's were performed on Aroclors 1221, 1232, 1242 and 1248.

The surrogate standard percent recoveries met acceptance criteria.

The method blanks were free of interference.

The matrix spike/matrix spike duplicate of a sample was not requested.

The laboratory control samples met acceptance criteria.

The PRRL's are adjusted for percent solids, dilution factors and extraction volumes as applicable.

The sampling to extraction holding time of fourteen days and extraction to analysis holding time of forty days was met for all samples.

CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G029

DATE: May 18, 2000

METALS REPORT:

The samples were analyzed for GE Apdx IX + 3 Metals by Method 6010A and Mercury by SW7470A.

The initial and continuing calibration verifications met acceptance criteria.

The LCS was acceptable.

The method blank was free of interference.

The sampling to analysis holding times were met for all samples.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.

SULFIDE REPORT:

The samples were analyzed for Sulfide by Method SW9030A. The result reported represents the total of soluble and in-soluble sulfide.

The LCS's met acceptance criteria.

The method blanks were free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.

CYANIDE REPORT:

The samples were analyzed for Cyanide by Method SW9012.

The LCS's met acceptance criteria.

The method blanks were free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed. Release of the data contained in the hard copy data package has been authorized by the Laboratory Manager or designee, as verified by the following signature.

Submitted by,

A handwritten signature in black ink that reads "Michele L. Rose". The signature is written in a cursive style with a large initial "M" and a long, sweeping tail.

Michele L. Rose
Project Manager

SAMPLE RECEIPT OBSERVATIONS:

The samples were received June 16, 1999 at 9:00 via FedEx in good condition. The receipt temperature was 5°C. The dioxin analysis was sub-contracted to Columbia Analytical Services with the approval of BBL. Additional volatile samples were received which were sampled June 14, 1999. They were not received with original Appendix IX + 3 samples.

CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G030

DATE: May 18, 2000

SEMIVOLATILES REPORT:

The samples were analyzed for GE App. IX + 3 Semivolatiles in accordance to the guidelines of method SW8270C.

The tunes, initial calibration and continuing calibration verifications met acceptance criteria.

The internal standard areas were within quality control criteria.

The surrogate standard percent recoveries were within quality control criteria.

The laboratory control sample met acceptance criteria.

The method blank was free of interference.

The PRRL's (reporting limits) are adjusted for percent solids and extraction volumes as applicable.

The sampling to extraction holding time of fourteen days and extraction to analysis holding time of forty days was met for all samples.

DATE: May 18, 2000

VOLATILES REPORT:

The samples were analyzed for GE App. IX + 3 Volatiles in accordance to the guidelines of Method SW8260B.

The tunes, initial calibration and continuing calibration verifications met acceptance criteria.

The surrogate standard percent recoveries and internal standard areas met acceptance criteria.

The laboratory control sample met acceptance criteria.

The method blank was free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The sampling to analysis holding time of fourteen days was met for all samples.

PCB REPORT

The samples were analyzed according to the guidelines of Method 8082.

The PCB responses were quantitated by the Aroclor multi-component analysis, using at a minimum three unique peaks of the pattern.

All initial calibration and continuing calibration verifications met acceptance criteria. The 5 pt. initial calibration consists of PCB 1016, 1260 and 1254/Surrogates. Single point pattern recognition's were performed on Aroclors 1221, 1232, 1242 and 1248.

The surrogate standard percent recoveries met acceptance criteria.

The method blanks were free of interference.

The laboratory control samples met acceptance criteria.

The PRRL's are adjusted for percent solids, dilution factors and extraction volumes as applicable.

The sampling to extraction holding time of fourteen days and extraction to analysis holding time of forty days was met for all samples.

CASE NARRATIVE

DATE: May 18, 2000

METALS REPORT:

The samples were analyzed for GE App. IX + 3 Metals by Method 6010A and Mercury by SW7470A.

The initial and continuing calibration verifications met acceptance criteria.

The LCS met acceptance criteria.

The method blank was free of interference.

The sampling to analysis holding times were met for all samples.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

SULFIDE REPORT:

The samples were analyzed for Sulfide by Method SW9030A. The result reported represents the total of soluble and in-soluble sulfide.

The LCS's met acceptance criteria.

The method blanks were free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.

CYANIDE REPORT:

The samples were analyzed for Cyanide by Method SW9012.

The LCS's met acceptance criteria.

The method blanks were free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.

I certify that this data package is in compliance with the terms and conditions of the contract, both technically and for completeness, for other than the conditions detailed. Release of the data contained in the hard copy data package has been authorized by the Laboratory Manager or designee, as verified by the following signature.

Submitted by,

A handwritten signature in black ink that reads "Michele L. Rose". The signature is written in a cursive style with a large, sweeping "M" and "R".

Michele L. Rose
Project Manager

SAMPLE RECEIPT OBSERVATIONS:

The samples were received June 17, 1999 at 9:00 via FedEx. One 40 ml vial for OPCA-MW-3 and one 40 ml vial for Rinse Blank was received broken. One amber liter for Rinse Blank and 2 amber liters for OPCA-MW-1 were received broken, also. All broken containers were replaced by the client. Per Steve Lewitt of BBL, CT&E was authorized to use the same sample date and time for replacement containers. The receipt temperature was 5°C. The dioxin analysis was sub-contracted to Columbia Analytical Services with the approval of BBL.

SEMIVOLATILES REPORT:

The samples were analyzed for GE App. IX + 3 Semivolatiles in accordance to the guidelines of method SW8270C.

The tunes, initial calibration and continuing calibration verifications met acceptance criteria.

The internal standard areas were within quality control criteria.

The surrogate standard percent recoveries were within quality control criteria.

The LCS met acceptance criteria.

The method blank was free of interference.

The PRRL's (reporting limits) are adjusted for percent solids and extraction volumes as applicable.

The sampling to extraction holding time of fourteen days and extraction to analysis holding time of forty days was met for all samples.

CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G033

DATE: May 18, 2000

VOLATILES REPORT:

The samples were analyzed for GE App. IX + 3 Volatiles in accordance to the guidelines of Method SW8260B.

The tunes, initial calibration and continuing calibration verifications met acceptance criteria.

The surrogate standard percent recoveries and internal standard areas met acceptance criteria.

The LCS met acceptance criteria.

The method blank was free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The sampling to analysis holding time of fourteen days was met for all samples.

CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G033

PCB REPORT

The samples were analyzed according to the guidelines of Method 8082.

The PCB responses were quantitated by the Aroclor multi-component analysis, using at a minimum three unique peaks of the pattern.

-All initial calibration and continuing calibration verifications met acceptance criteria. The 5 pt. initial calibration consists of PCB 1016, 1260 and 1254/Surrogates. Single point pattern recognition's were performed on Aroclors 1221, 1232, 1242 and 1248.

The surrogate standard percent recoveries met acceptance criteria.

The method blanks were free of interference.

The LCS met acceptance criteria.

The PRRL's are adjusted for percent solids, dilution factors and extraction volumes as applicable.

The sampling to extraction holding time of fourteen days and extraction to analysis holding time of forty days was met for all samples.

**CASE NARRATIVE
ON SITE CONSOLIDATION
Project No: 201.85.02
CT&E Laboratory Number: G39-F0-G033**

DATE: May 18, 2000

METALS REPORT:

The samples were analyzed for GE App. IX + 3 Metals by Method 6010A and Mercury by SW7470A.

The initial and continuing calibration verifications met acceptance criteria.

The LCS was met acceptance criteria.

The method blank was free of interference.

The matrix spike/duplicate of the sample met all acceptance criteria with the exception of Tin, which failed low with a recovery of 72%. The matrix spike was not reanalyzed due to the method blank, sample and duplicate being free of interference and the laboratory control sample meeting acceptance criteria.

The sampling to analysis holding times were met for all samples.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

SULFIDE REPORT:

The samples were analyzed for Sulfide by Method SW9030A. The result reported represents the total of soluble and in-soluble sulfide.

The LCS met acceptance criteria.

The method blanks were free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.

CYANIDE REPORT:

The samples were analyzed for Cyanide by Method SW9012.

The LCS met acceptance criteria.

The method blanks were free of interference.

The PRRL's (reporting limits) are adjusted for percent solids as applicable.

The holding time was met for all the samples.
