SECTION 1
INTRODUCTION

This Sampling Report describes efforts by the U.S. Environmental Protection Agency (EPA) to characterize ambient water at varying depths at a Great Lakes ballast water loading port. The objective of the sampling and analysis activities was to determine whether the characteristics of ambient water drawn near the lake bed through low sea chests on Great Lakes bulk carriers (Lakers[1]) would meaningfully differ from those of ambient water withdrawn higher in the water column through the Lakers' side sea chests. The sampling took place on May 28, 2014 at the Port of Indiana - Burns Harbor on Lake Michigan under the direction of the Office of Wastewater Management of the EPA.

Samples were collected in accordance with procedures specified in the *Sampling and Analysis Plan for the Vessel General Permitting Program Ballast Water Intake Characterization Sampling* (SAP) and the *Quality Assurance Project Plan for Technical Support for the Vessel General Permitting Program – Ballast Water Intake Characterization Sampling* (QAPP). Samples collected for analysis of turbidity were analyzed on-site by Eastern Research Group, Inc. (ERG), and samples collected for analysis of total suspended solids and particulate organic carbon were analyzed by TriMatrix Laboratories in Grand Rapids, Michigan. The SAP is provided in Appendix A.

Section 2.0 describes the sample collection methods and deviations from the SAP. Section 3.0 presents and analyzes the analytical data collected during the sampling episode. Section 4.0 describes the quality assurance and quality control (QA/QC) procedures and results, and Section 5.0 presents references used in this document.

1.1 BACKGROUND

This sampling episode is part of EPA's on-going efforts to minimize the release of non-indigenous invasive species in ballast water discharges to the Great Lakes. Part 2.2.3.3 of EPA's 2013 Vessel General Permit (VGP) require vessels, where feasible, to use the high sea suction when the clearance is less than 5 meters (approximately 15 feet) to the lower edge of the sea chest, or when the vessel is dockside, to reduce sediment intake. Also, Part 2.2.3.4 of the VGP requires Lakers to minimize complete ballasting dockside and wait until the vessel is in deeper water when practical and safe to further reduce sediment uptake. These permit requirements assume that sediment concentrations are higher nearer the lake bottom than they are at the top of the water column, and that ballast water pulled from lower in the water column is more likely to result in higher concentrations of sediment deposited into ballast tanks.

Vessel operators have confirmed EPA's assumptions anecdotally. A senior representative from American Steamship Company, which currently operates 17 Lakers, has noted that uptake

[1] "Laker" is the common name for the large and uniquely designed and constructed dry bulk vessels (or carriers) used to transport bulk material commodities throughout the Great Lakes system. Thousand-foot Lakers transport goods on only the four upper Great Lakes and connecting channels, as these vessels are limited by their size from transiting the Welland Canal. Smaller "Lakers" also serve Lake Erie, and in some cases, they exit the St. Lawrence Seaway to serve ports on the St. Lawrence River, or act as seagoing vessels by serving as vessels engaged in coastal trade along the Canadian or U.S. Atlantic seaboard. The primary commodities transported by the Lakers include iron ore pellets, coal, grain, limestone, cement, sand, and salt.

of ballast during cargo off-loading is generally delayed as long as possible to raise the level of the ballast intake sea chests as far above the bottom of the slip/dock as possible in an effort to reduce sediment uptake. He also added that one of their Lakers, the Walter J. McCarthy Jr, was retrofit with ballast intake sea chests at a vertical position much closer to the water line than the ship's original sea chest location on the bottom shell of the ship, and that raising the sea chest has significantly reduced the amount of sediment drawn in with ballast water.[2]

EPA's intent with these BMPs is to limit the amount of sediment potentially containing live aquatic organisms being drawn into ballast tanks during ballasting in Great Lakes ports. Sediments have been shown to harbor living organisms including resting stages – eggs, spores and cysts (Johengen et al., 2005), and these organisms can then be transported between Great Lakes ports in ballast tank sediments. During ballast water discharge, a portion of the sediments can be discharged resulting in the potential to spread non-indigenous invasive species among multiple Great Lakes ports. Additionally, sediment in suspension in the ballast water reduces the effectiveness of UV radiation and ultrasonic treatments and requires significantly higher dosages of chlorine, ozone, hydrogen peroxide, and other chemicals for effective treatment (Sano et al., 2003 and 2004).

1.2 OBJECTIVES AND SCOPE

The primary objective of this sampling program is to collect primary data that will be used to:

- Determine if water taken dockside and collected from lower in the water column has a higher concentration of sediment than water collected from higher in the water column;
- Determine whether the suction created by the ballast pumps on Lakers increases sediment intake; and
- Determine if the amount of sediment transferred into ballast tanks on Lakers would decrease if vessels collected ballast water from higher in the water column (e.g., by using side or upper sea chests) rather than closer to the lake bottom (e.g., by using bottom or lower sea chests).

1.3 PORT LOCATION SELECTION

EPA selected the Port of Indiana at Burns Harbor (Burns Harbor) for collection of samples based on the number of bulk cargo vessels (both Lakers and over-seas vessels) entering the port annually, its location on Lake Michigan where turbidity levels are less influenced by precipitation events as compared to ports located within a river system, and accessibility of the port by EPA's ERG sampling team. Figure 1-1 is a diagram of the port at Burns Harbor. Dock location 4 on the East Harbor Arm within the port of Burns Harbor was selected for sampling because this location is frequently used by Lakers to off-load bulk cargo and load ballast water,

[2] Information provided by Mr. Noel Basset, Vice President of Operations of American Steamship Company on November 14, 2014 in response to EPA's questions regarding management of sea chests and sediment on board Lakers.

and because no vessels were scheduled to arrive at this dock location during the sampling period.[3]

SECTION 2
SAMPLE COLLECTION METHODS

This section describes the sampling procedures used to collect ambient water samples at various depths using a Kemmerer sampler and a simulated ballast pump to determine if sediment concentrations change with depth and whether pumping of ballast water increases sediment loads.

2.1 SAMPLE COLLECTION METHODOLOGY

The sampling team collected samples at various depths from the ambient water adjacent to a pier in Burns Harbor where Lakers typically load ballast water. The sampling team used two separate techniques performed sequentially. Using the first technique, the sampling crew collected discrete grab samples of the water column using a Kemmerer sampler to determine the concentrations of suspended solids, particulate organic carbon, and turbidity. This first sampling technique was intended to collect water column samples relatively quiescently, with minimal suspension of sediment from the lake/river bottom. For the second technique, the sampling team then used a pump to extract ambient water at the same depths as the Kemmerer sampler to determine if the suction created by the pump resulted in increased concentrations of turbidity, suspended solids and particulate organic carbon in the samples. This second technique was intended to simulate ballasting by a vessel, including using a similar pump type and pumping rates as full-scale vessel ballast pumps (see further discussion in Part 2.1.2).

Samples were collected at 4-foot intervals with both the Kemmerer sampler and the pump, beginning at a depth of 6 feet below the lake surface and ending at a depth of 22 feet below the lake surface. The distance to the water surface from the top of the seawall was 14 feet. A total of 3 replicates sample sets were collected, with each replicate set of samples (Kemmerer and pump) being collected at a location on the pier 60 feet from the previous sample set to prevent sediment which may have been re-suspended during collection of the previous sample set from impacting the subsequent sample sets. Figure 2-1 depicts the Kemmerer and pump sampling depths and locations. Figure 2-2 shows the spatial relationship between the three sampling locations.

Normal sea chest intake occurs between 12 and 14 feet below the waterline; however, when dockside, the sea chest operates anywhere from 1 to 15 feet (Noel Basset, Personal communication). In extreme cases the raised side sea chest intake may reach 2 feet above the waterline when the vessel has no cargo.[4] The total depth of the lakebed at the sampling locations was 23 feet. For perspective, the minimum depth that American Steamship Line vessels can operate in is 22 feet, so that the propellers are fully immersed.[4]

[4] Information provided by Mr. Noel Basset, Vice President of Operations of American Steamship Company on November 14, 2014 in response to EPA's questions regarding management of sea chests and sediment on board Lakers.

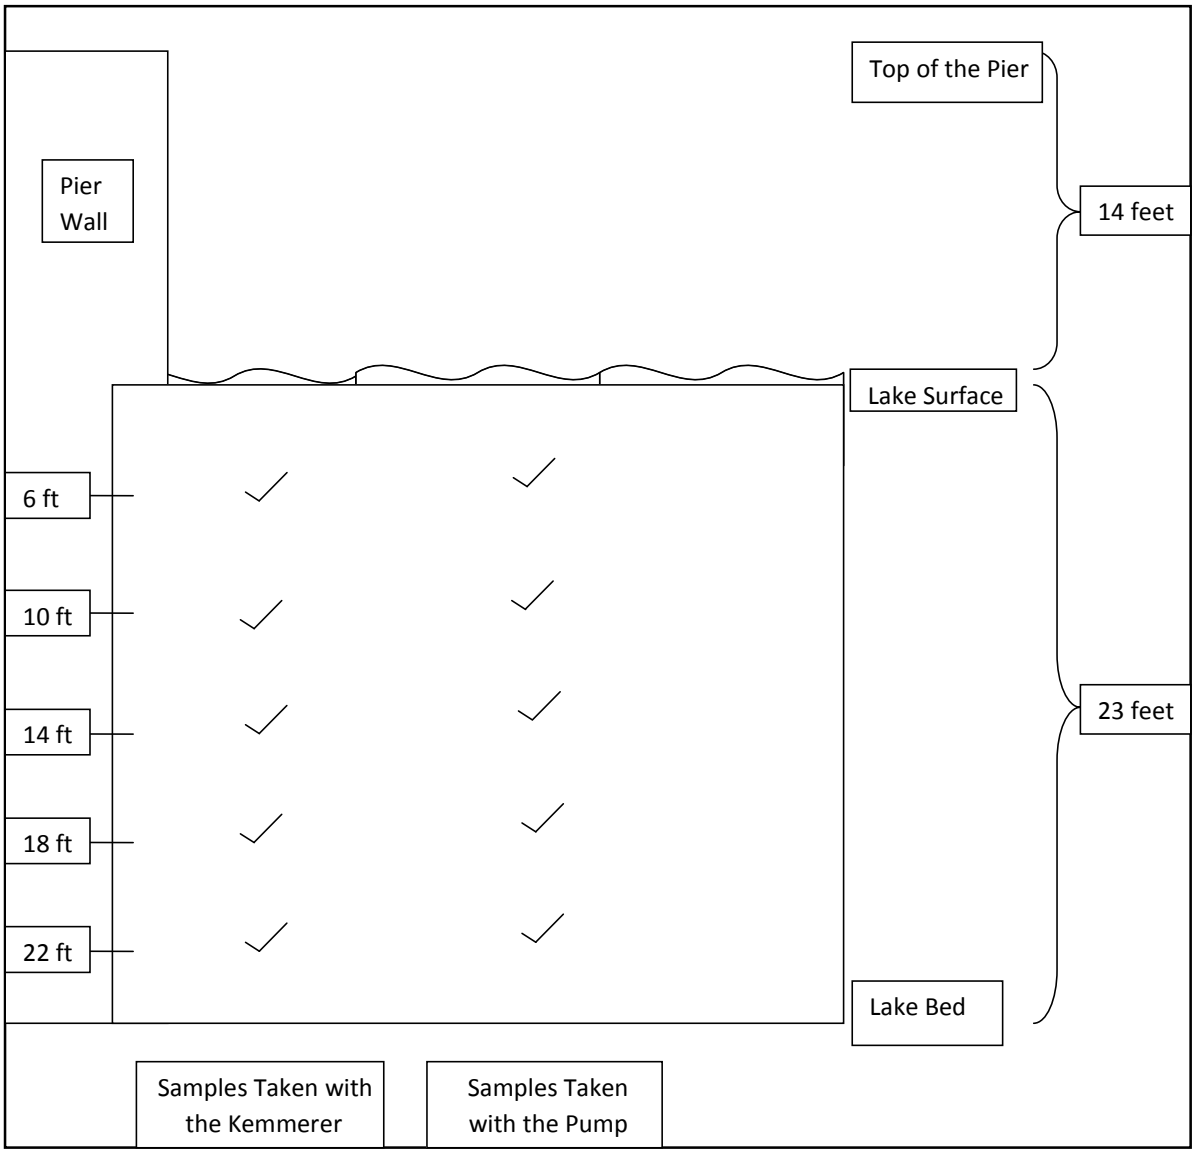

Figure 2-1. Sampling Depths and Pier Height at Burns Harbor During Sample Collection

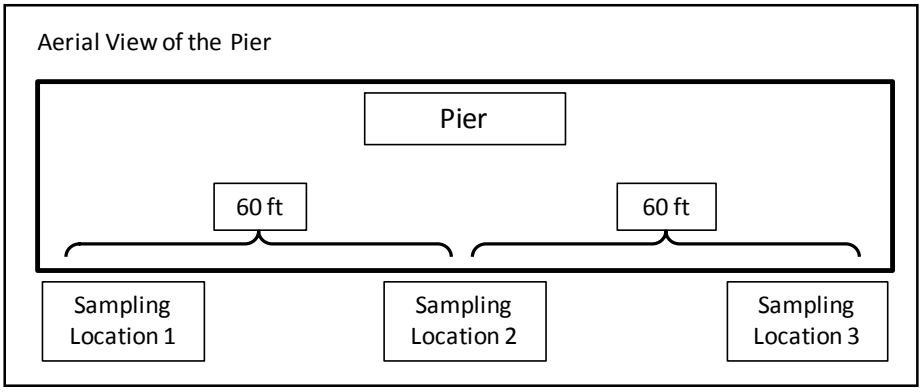

Figure 2-2. Spatial Relationship Between the Three Replicate Sampling Locations

2.1.1 Kemmerer Sampling

Samples were collected using a 1.2-liter Kemmerer sampler lowered to the target depth and then closed to collect a discrete sample. A rope attached to the Kemmerer sampler having pre-measured 4 foot increments was used to ensure the sampler was lowered to the desired depths. Once the Kemmerer sampler was closed, the water sampler was brought to the surface and the sample drained directly into the appropriate sample bottles. The process was repeated at each target depth until all the sample bottles were filled.

2.1.2 Pump Sampling

The sampling pump used to simulate a Laker ballast pump was a Honda gasoline powered centrifugal trash pump with a 2-inch diameter flexible intake hose. EPA selected this pump because it uses the same centrifugal pumping technology as ballast pumps used onboard Lakers. According to design data for Lakers, ballast water pumping rates for centrifugal pumps range between 30.6 and 42.6 gpm/in^2 based on pipe sizes ranging between 10 inches and 30 inches in diameter (USGS, 2013). Using these design data, ballast pumping rates onboard Lakers average 36.6 gpm/in^2. Therefore, the target pump rate for the portable pump was 115 gpm, which provides a pumping rate of approximately 36.6 gpm/in^2 through the 2" suction hose.

Prior to sampling, the pump flow rate was calibrated to ensure the pumping rate would be similar to that of a Laker ballast pump. To calibrate the pump, the flexible intake hose was lowered over the seawall and into the water column to a depth of 10 feet and the pump started. Once the pump was operating at steady state conditions, as determined by the consistency of the water stream from the discharge hose, the time was recorded to fill a 30-gallon plastic trash container. Based on an average time of 15 seconds to fill the 30-gallon plastic container, EPA estimated the pump flow rate to be 120 gallons per minute (gpm) at the hydrostatic head conditions observed during sample collection. For a 2-inch diameter flexible suction hose and a measured flow rate of 120 gpm, the flow rate per area of hose was calculated to be 38.2 gpm/in^2. Since the measured flow rates per area from the pump were within 5 percent of the target flow rate per area of 36.6 gpm/in^2 needed to simulate a Laker ballast pumping rate, EPA considered the flow rate to be appropriate for testing.

The flexible intake hose was then lowered into the water column to premeasured depths, and the pump was allowed to operate for 1 minute to flush the intake and discharge hoses before a sample was collected in a 5-gallon plastic pail. The sample from the pail was immediately poured into individual sample bottles, which were submitted to the laboratory for analysis of total suspended solids and particulate organic carbon. During pour-off into the individual sample bottles, the pail was manually shaken and swirled to prevent solids from settling.

Note that while the overall design and pumping rates of the simulated and actual Laker ballast pumps are similar, there are significant differences between these pumps in physical size and configuration. For example, the ballast pump on some Interlake Steamship Company vessels have 30-inch diameter impellers with a 30^o blade angle, a 2.5-inch gap between the outer edge of the impeller and the cavity walls and operate at speeds of 690 revolutions per minute (RPM).[5] In

[5] Main ballast pump design data provided by Phil Moore at Interlake Steamship Company to Mark Briggs at ERG via email on July 11, 2014.

contrast, the impeller diameter on the pump used for this study was 5 inches and had a 0.008 to 0.014 inch gap between the outer edge of the impeller and the cavity walls. The angle of the blades and the speed of the impeller in the pump used in this study were unknown. However, these differences in physical size and configuration are not expected to impact the concentrations of suspended solids, particulate organic carbon, and turbidity of the water pulled through the two types of pumps; concentrations of these constituents are believed to be impacted primarily by the pump suction created by the pumping rate (target 36.6 gpm/in^2).

2.2 SAMPLE ANALYSIS METHODOLOGY

Samples collected from both the Kemmerer sampler and the pump were analyzed for total suspended solids (TSS), particulate organic carbon (POC) and turbidity. Samples collected for analysis of TSS and POC were analyzed by TriMatrix Laboratories using the analytical methods shown in Table 2-1. Due to the short holding time for turbidity (24 hours), samples for turbidity were analyzed in the field using Standard Method 2130 B.

Table 2-1. Analytical Methods and Detection Limits for Sampled Analytes

Analyte	Method Number	MDL	Units
Total Suspended Solids (TSS)	SM 2540 D	1	mg/L
Particulate Organic Carbon (POC)	LG-207[a]	1.1	mg/L
Turbidity	SM 2130 B	0.05	NTU

SM = Standard Methods.

MDL = Method Detection Limit.

NTU = Nephelometric Turbidity Units.

[a] Method LG-207 developed by USEPA GLNPO for measuring POC in the Great Lakes.

2.3 QUALITY ASSURANCE/QUALITY CONTROL

Laboratory and field quality control was evaluated by analyzing duplicate samples and calculating the relative percent difference (RPD). Duplicate laboratory and field analytical data are discussed in Sections 4.1 and 4.2, respectively. Other field quality control samples prepared for this sampling episode included an equipment blank which is discussed in Section 4.2.1.

2.4 DEVIATIONS FROM THE SAMPLING AND ANALYSIS PLAN

The sampling episode proceeded as specified in the SAP with the deviations described in Table 2-2.

Table 2-2. Deviations from the Sampling and Analysis Plan

Deviation	Description
Sampling Depth and Sampling Interval	The water depth of the harbor on the day of sampling was 23 feet and not 28 feet as anticipated in the SAP. As a result, the first sample was collected at a depth of 6 feet below the water surface and then subsequently at 4 foot intervals to a depth of 22 feet. Figure 3-1 in the SAP was based on a total water depth of 28 feet and therefore samples were anticipated to be collected at 5-foot intervals to a depth of 28 feet, with the first sample beginning at 8 feet below the water surface.
Laboratory and Field Duplicates	ERG had intended to collect extra volume for the laboratory to perform a duplicate analysis of selected samples; however, the extra sample volume was not collected. Instead, the extra volume collected for field duplicate analysis was analyzed and used to evaluate both laboratory precision and field precision. The result is there were no blind field duplicates provided to the laboratory.
MS/MSD for POC	The SAP and associated QAPP had intended for the laboratory to conduct matrix spike and matrix spike duplicate (MS/MSD) analysis of POC samples; however, the analytical method does not allow for MS/MSD analysis for quality control. Instead, the method relies on analysis of laboratory duplicate samples. Accordingly, ERG amended the QAPP to incorporate this change.

SECTION 3
RESULTS AND DISCUSSION

This section presents the data collected during this sampling episode. Analytical results for turbidity, TSS and POC from both the Kemmerer sampler and the pump at each sampling depth and each sampling location are presented in Section 3.1. Section 3.2 is a summary of the data including graphic representations along with a discussion of how the data may be used to compare sediment loading into Laker ballast tanks if high-suction sea chests are used rather than low-suction sea chests. All raw analytical data provided by the contract laboratory is provided in Appendix B of this report.

3.1 LABORATORY AND FIELD ANALYTICAL RESULTS

Analytical results for turbidity, TSS and POC at the three sampling locations are provided in Table 3-1 through Table 3-3. The three tables represent the three locations where samples were collected on the pier at Burns Harbor (see Figure 1-1). The locations are separated by approximately 60 feet to prevent sediments that may have been disturbed by the pump from being entrained into the next sample set.

Turbidity was detected in the Kemmerer sampler equipment blank (flagged by a "b" in Table 3-1 through Table 3-3; see Table 4-2 for equipment blank results). Both TSS and turbidity were detected in the pump equipment blank (flagged by a "c" in Table 3-1 through Table 3-3; see Table 4-2 for equipment blank results). The small amounts of turbidity and TSS in the equipment blanks may have contributed to a minor portion of the TSS and turbidity measured in the samples.

Table 3-1. Sample Results for Location 1

	Kemmerer Sampler				Pump			
Sample Depth (ft)[a]	Sample No.	TSS (mg/L)	POC (mg/L)	Turbidity[b] (NTU)	Sample No.	TSS[c] (mg/L)	POC (mg/L)	Turbidity[c] (NTU)

[c] TSS and turbidity were detected in the pump equipment blank at concentrations of 6 mg/L and 1.7 NTU, respectively.

[d] Average of duplicate data. Duplicate samples collected to determine precision.

3.2 DATA ANALYSIS AND DISCUSSION

To analyze the data from the three separate locations, EPA averaged the Kemmerer data at each depth and the pump data at each depth (see Table 3-4). For TSS and POC results less than the detection limit, EPA used one-half the detection limit in calculations. EPA also plotted the average TSS, POC and turbidity data by depth (see Figure 3-1, Figure 3-2 and Figure 3-3, respectively.

Table 3-4. Average (± 1 Standard Deviation) Sample Results for All Locations

Sample Depth (ft)[b]	Kemmerer Sampler[a]			Pump[a]		
	TSS (mg/L)	POC (mg/L)	Turbidity[c,e] (NTU)	TSS[d] (mg/L)	POC (mg/L)	Turbidity[d,e] (NTU)
6	2.9 ± 2.2	0.55 ± 0.0	2.4 ± 0.8	1.9 ± 0.5	0.55 ± 0.0	2.3 ± 0.5
10	1.7 ± 0.4	0.55 ± 0.0	2.7 ± 0.04	3.9 ± 3.1	0.64 ± 0.2	3.5 ± 2.1
14	1.8 ± 1.1	0.55 ± 0.0	1.9 ± 0.8	5.7 ± 6.4	0.55 ± 0.0	2.6 ± 0.5
18	1.8 ± 0.4	0.55 ± 0.0	1.9 ± 0.6	32.0 ± 29.8	1.0 ± 0.8	35.6 ± 28.6
22	2.3 ± 0.1	0.87 ± 0.6	2.8 ± 0.7	58.4 ± 15.6	2.6 ± 0.4	69.3 ± 15.7

[a] Average calculated from three locations. For concentrations less than the method detection limit, one-half the method detection limit was used in calculating average concentrations.

[b] Depth below the water surface.

[c] Turbidity was detected in the Kemmerer equipment blank at a concentration of 0.6 NTU.

[d] TSS and turbidity were detected in the pump equipment blank at concentrations of 6 mg/L and 1.7 NTU, respectively.

[e] NTU = Nephelometric Turbidity Units

As expected, the data presented in Table 3-4 and shown graphically in Figure 3-1, Figure 3-2 and Figure 3-3 verify that pumping ballast water near the lake bed significantly increases the amount of suspended solids, POC, and turbidity drawn into ballast tanks when compared to pumping ballast water from higher in the water column. TSS and turbidity levels entering the pump intake within 1 foot of the lake bottom were more than 10 times greater than those at intake depths in the middle of the water column. POC concentrations in ballast water would more than double near the lake bed as compared to the middle of the water column. These data also show that, for the port at Burns Harbor, there does not appear to be a discernable direct relationship between TSS and POC during this sampling event.

The results also show that the vacuum action caused by the pump significantly increases TSS, turbidity, and POC as compared to the quiescent sampling technique employed using the Kemmerer sampler. Even near the lake bed, concentrations of TSS and turbidity in samples collected by the Kemmerer were more than 40 times lower than those in samples collected with the pump. POC concentrations in samples collected near the lake bed using the Kemmerer sampler were 3 times lower than POC concentrations in samples collected by the pump at the same depth.

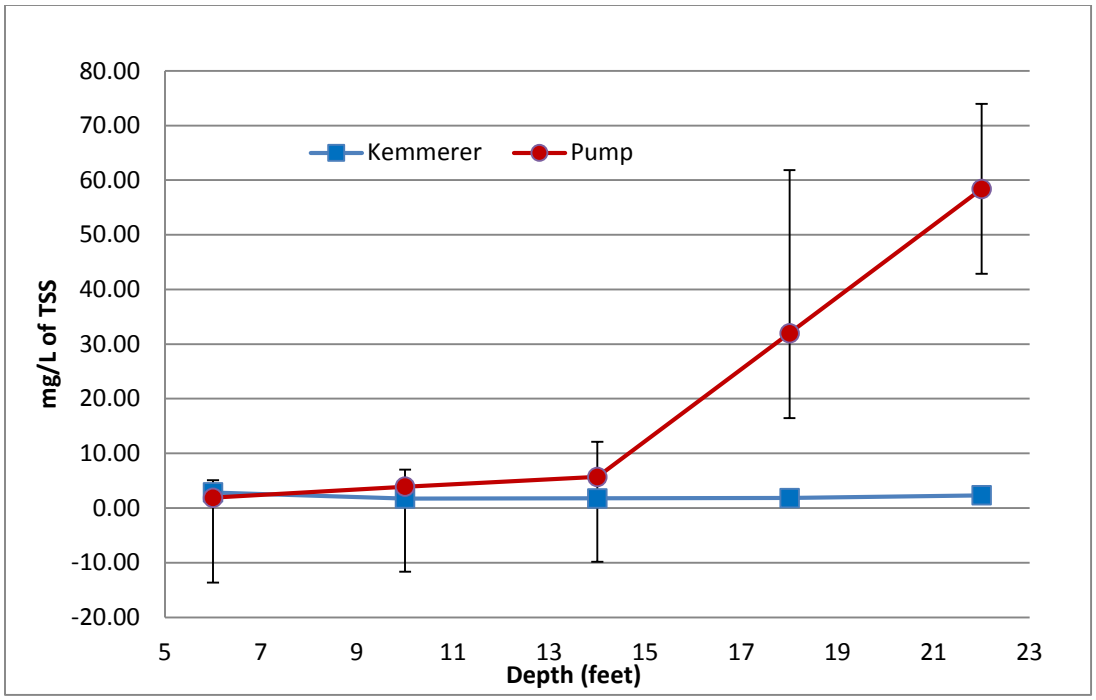

Figure 3-1. TSS Concentration (± 1 Standard Deviation) with Depth and Sampling Technique

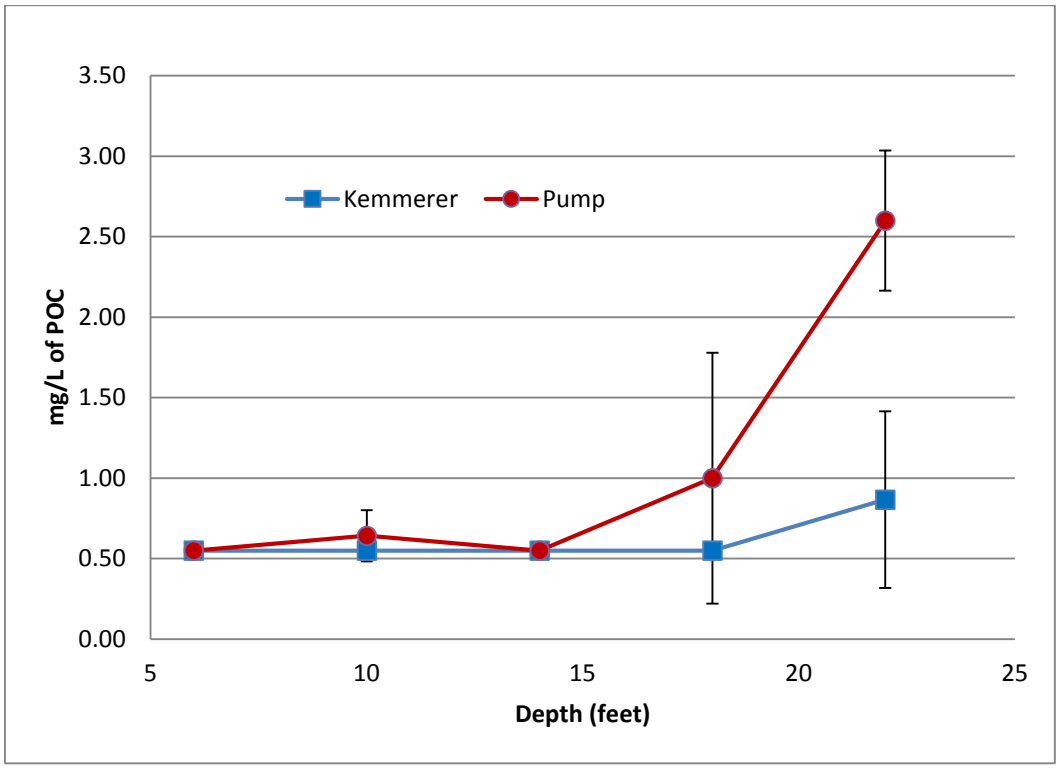

Figure 3-2. Particulate Organic Carbon Concentration (± 1 Standard Deviation) by Depth and Sampling Method

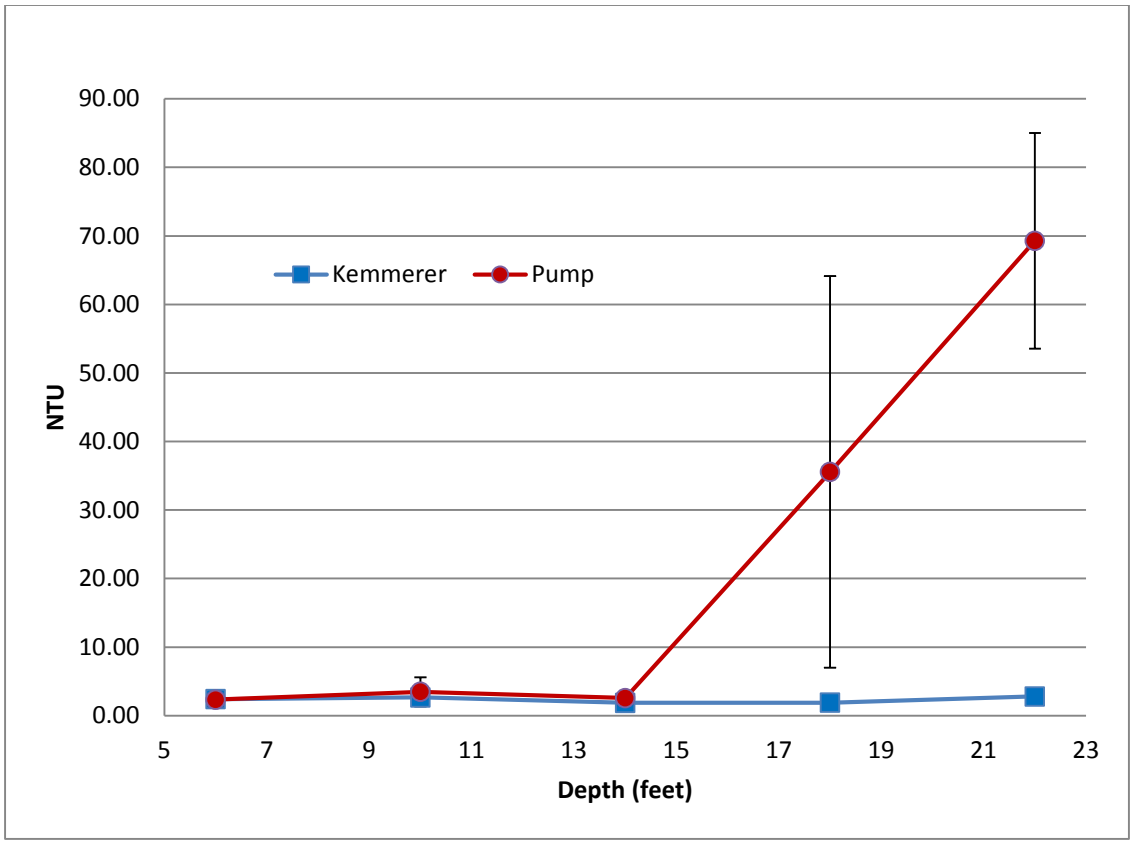

Figure 3-3. Turbidity Concentration (± 1 Standard Deviation) by Depth and Sampling Method

For Lakers ballasting in locations such as Burns Harbor, using high sea chests rather than low sea chests could have a significant impact on the amount of sediment entering ballast tanks. For example, large capacity thousand foot class Lakers have a total ballast capacity of 62,000 metric tons (mt) (16,365,000 gallons) (USCG, 2013). If a Laker withdraws 62,000 metric tons of ballast water through their bottom sea chest at Burns Harbor, extrapolating from these bench scale results, the vessel could also be drawing nearly 0.75 metric tons of suspended solids into the ballast tanks, a portion of which will likely settle in the vessel's ballast tanks. However, if the same Laker draws 62,000 metric tons of ballast water through a side sea chest located in the mid-point of the water column (e.g., 10 to 14 feet below the water surface), extrapolating from these bench scale results, the suspended solids drawn into the ballast tanks could decrease to approximately 0.06 metric tons.

SECTION 4
DATA QUALITY

QA/QC procedures applicable to this sampling episode are outlined in the QAPP for this program, approved by EPA on May 16, 2014, and its amendment dated May 23, 2014. This section describes the quality control (QC) practices used to assess the precision and accuracy of the analytical data presented in Section 3.0. QC practices used for this sampling episode include the analysis of duplicate samples and QC standard checks.

4.1 ANALYTICAL QUALITY CONTROL

EPA verified that laboratory performance was acceptable by verifying that all samples received by the laboratory were analyzed within the method-specific holding times and that the quality checks of the analytical data, as specified by the QAPP, were conducted. Data review chemists from the contract laboratory prepared written data review narratives (Appendix C) describing any qualifications of the analytical data. The following summarizes the laboratory analytical QC measures for analysis of TSS, POC, and turbidity samples.

4.1.1 Laboratory Duplicate Sample Analysis

Laboratory duplicate samples were analyzed for TSS, POC, and turbidity at a frequency of 10 percent, and the RPDs between the duplicate samples were calculated to determine if the target of $\pm$ 20 percent was achieved. TSS and POC samples were analyzed by the contract laboratory, and turbidity samples were analyzed in the field by the sampling team. Table 4-1 shows the results of the duplicate sample analysis and the calculated RPDs. For the laboratory duplicate samples, the laboratory analyzes two separate sample volumes collected by the field crew for a specific sampling depth and location and compares the results to evaluate precision. For this study, the field duplicate samples also served as the laboratory duplicate samples.

Table 4-1. Duplicate Sample Results and RPDs

Sample No.	TSS (mg/L)	TSS Dup (mg/L)	TSS RPD (%)	POC (mg/L)	POC Dup (mg/L)	POC RPD (%)	Turbidity (NTU)	Turbidity Dup (NTU)	Turbidity RPD
022	1.7	1.4	19.4	ND (1.1)	ND (1.1)	NC	3.1	2.1	38.5
023	13.1	7.1	59.4	ND (1.1)	ND (1.1)	NC	2.1	9.7	-128.8
024	2.3	1.6	35.9	ND (1.1)	ND (1.1)	NC	2.5	3.0	-18.2

NTU = Nephelometric Turbidity Units

ND = Not detected (number in parentheses is detection limit).

NC = Not calculated.

For POC, all results were below detection; however, for TSS and turbidity, the RPD was achieved for only 1 of the 3 duplicate samples. According to the contract laboratory's data review narratives for TSS (Appendix B), RPDs calculated from sample results that are less than 5 times the method detection limit (MDL) of 1 mg/L should not be considered as quantifiable. For sample 023, the sample results are greater than 5 times the MDL, and therefore the RPD of

59.4 percent is valid but outside the ± 20 percent target. Although the RPDs for two of the three TSS and turbidity duplicates are outside the target range, ERG recommended that EPA consider the entire data usable since ERG's experience is that achieving the target RPD for TSS and turbidity for duplicate samples is difficult at low concentrations. TSS and turbidity measure suspended particles, and any particles that are collected in the large receiving vessel are then split between two sample bottles. Small variations in the number of particles entering the two duplicate sample bottles can result in different concentrations. At the low concentrations measured in the duplicate sample bottles, slight differences result in the calculated RPDs becoming elevated.

4.1.2 Laboratory Quality Control Standards

The contract laboratory prepares and analyzes laboratory control standards (LCS) that include method blanks and method blanks that have been spiked with specific concentrations to verify recoveries. Method blanks are included with each batch of samples and are prepared by analyzing Millipore water that is processed through the same procedure as the samples. None of the method blanks analyzed by the laboratory had either TSS or POC concentrations above their respective method detection limits. Table 4-2 provides the method blank spike recoveries prepared by the laboratory. As indicated in Table 4-2, the blank spike recovery results for both TSS and POC are within the QC limit recovery ranges specified by the laboratory.

Table 4-2. Method Blank Spike Recoveries

Analyte	Spiked Concentration (mg/L)	Analyzed Concentration (mg/L)	Recovery (%)	QC Limit Recovery Range (%)
TSS	200	199	100	88 – 104
TSS	200	199	100	88 – 104
POC	3.14	3.02	96	0 - 200

For POC analysis, the contract laboratory also prepares and analyzes initial and continuing calibration check standards to verify the method is providing accurate analytical results. Table 4-3 shows the calibration check standard results for POC. All calibration check standards are within the QC limit recovery range.

Table 4-3. Calibration Check Standard Results

Analyte	Spiked Concentration (mg/L)	Analyzed Concentration (mg/L)	Recovery (%)	QC Limit Recovery Range (%)
POC	33.4	33.3	100	± 20
POC	29.1	29.1	100	± 20
POC	28.9	29.6	103	± 20
POC	25.4	25.6	101	± 20
POC	33.6	34.6	103	± 20
POC	28.7	29.6	103	± 20

4.2 FIELD QUALITY CONTROL

Field QC is monitored by preparing equipment blank samples and field duplicate samples. Each of these field QC measures is provided in the subsections below.

4.2.1 Equipment Blanks

The sampling team collected equipment blanks to assess the potential introduction of contaminants by sample collection equipment. Equipment blanks were prepared by filling the sampling equipment with Millipore water provided by TriMatrix Laboratories and then collecting that water in the appropriate sample bottles and submitting those samples to the laboratory for analysis. The sample collection equipment used to collect the equipment blanks were the same as those used at the sampling locations: the Kemmerer sampler and the pump with its associated hose and transfer lines. Table 4-4 shows the equipment blank results for the Kemmerer sampler and the pump.

Table 4-4. Equipment Blank Results for the Kemmerer Sampler and Pump

Equipment	Sample No.	Analysis	Units	Concentration
Kemmerer	035	TSS	mg/L	ND (1.0)
Kemmerer	035	POC	mg/L	ND (1.1)
Kemmerer	035	Turbidity	NTU	0.6
Pump	036	TSS	mg/L	6.0
Pump	036	POC	mg/L	ND (1.1)
Pump	036	Turbidity	NTU	1.7

ND = Not detected (number in parentheses is detection limit).
NTU = Nephelometric Turbidity Units

The equipment blank results for the Kemmerer sampler indicate the equipment was not introducing either TSS or POC to the samples. The Kemmerer may be adding 0.6 NTU of turbidity to the samples.

Turbidity and TSS measured in samples collected by the pump and its associated hose and transfer lines may be influenced by the collection equipment. The data in Table 4-4 shows TSS concentrations of 6.0 mg/L in the equipment blank. Therefore, up to 6 mg/L of the TSS measured in samples collected by the pump may be attributed to the sampling equipment. Turbidity measured in the pump and associated equipment was 1.7 NTU. Therefore, up to 1.7 NTU of the turbidity measured in samples from the pump may be attributed to the pump and associated hoses.

4.2.2 Field Duplicate Samples

Field duplicate samples were collected to assess the precision of the entire sample collection, handling, preparation, and analysis process. For this study, field duplicates were prepared by collecting the ambient water in the receiving container and then pouring this water into two separate sample containers. When transferring the water between the receiving container and the sample bottles, the receiving container was continuously swirled to prevent solids from settling. As stated previously, the field duplicate samples also served as the

laboratory duplicate samples since the analytical methods for duplicates do not require additional procedures or changes to the sample matrix. The RPDs between the two duplicate sample results are calculated and compared to the data quality objective. For this program, the QAPP provides an RPD target for field duplicate samples as less than 30% for TSS, POC, and turbidity. Table 4-5 shows the duplicate sample results.

Table 4-5. Field Duplicate Sample Results

Analyte	Unit	Sample Numbers		Original Result	Duplicate Result	RPD (%)
		Original	Duplicate			
TSS	mg/L	022	034	1.7	1.3	26.7
POC	mg/L	022	034	ND (1.1)	ND (1.1)	NC
Turbidity	NTU	022	034	3.1	2.1	38.5
TSS	mg/L	023	032	13.1	7.1	59.4
POC	mg/L	023	032	ND (1.1)	ND (1.1)	NC
Turbidity	NTU	023	032	2.1	9.7	129
TSS	mg/L	024	033	2.3	1.6	35.9
POC	mg/L	024	033	ND (1.1)	ND (1.1)	NC
Turbidity	NTU	024	033	2.5	3.0	18.2

ND = Not detected (number in parentheses is detection limit).

NC = Not calculated.

NTU = Nephelometric Turbidity Units

The field duplicate results in Table 4-5 show the TSS and turbidity RPDs for two duplicate samples were outside the 30% target. Although the RPDs for these samples are outside the target, EPA believes all the data collected for this study are usable. ERG noted to EPA that, based on their experience, achieving the target RPDs for TSS and turbidity for duplicate samples is difficult at low concentrations. TSS and turbidity measure suspended particles, and any particles that are collected in the large receiving vessel are then split between two sample bottles. Small variations in the number of particles entering the two duplicate sample bottles can result in different concentrations. At the low concentrations measured in the duplicate sample bottles, slight differences result in the calculated RPDs becoming elevated.

1. INTRODUCTION

The U.S. Environmental Protection Agency (EPA) is conducting a sampling program to evaluate the environmental benefits of loading ballast water from higher in the water column on Great Lakes bulk carriers (Lakers)[1]. This sampling plan provides general sampling procedures and methods to be followed when conducting sampling activities at a selected ballast water loading port. Sampling will be performed by EPA and/or EPA's technical contractor Eastern Research Group, Inc. (ERG), who will collect samples of lake water off the dock of a selected Great Lakes port. This document, in combination with the addendum to the Quality Assurance Project Plan (QAPP), is intended to serve as a guide to the field sampling crews, as well as a study review mechanism for EPA personnel.

1.1 Background

The intake of ambient water into ballast tanks for vessel ballasting activities results in the uptake of sediment which can accumulate in ballast tanks as sediments settle out of the water while stored in ballast tanks. The accumulation of sediment entrained into ballast tanks during uptake is especially problematic because it reduces the effectiveness of ballast-exchange treatment and other treatment approaches and serves as a reservoir for some live aquatic organisms including resting stages – eggs, spores, and cysts (Johengen, 2005). Ballast tank sediments may contain live aquatic organisms in resting stages (eggs, spores, and cysts) that are resistant to adverse conditions and accumulated over numerous previous ballasting operations making ballast-exchange less effective. Additionally, sediment in suspension in the ballast water reduces the effectiveness of UV radiation and ultrasonic treatments and requires the addition of significantly higher dosages of chlorine, ozone, hydrogen peroxide, and other chemicals currently under consideration for treatment approaches (Sano et al. 2003, 2004).

Conditions in Part 2.2.3.3 of the Vessel General Permit (VGP) (USEPA, 2013) require vessels to use best management practices (BMPs) to lighten the ship as much as practical in order to elevate water intakes (sea chests) before ballasting. This requirement is intended to minimize sediment uptake while accounting for boom list, hull stress, and bending moments. Another BMP at VGP Part 2.2.3.4 requires Lakers to forgo complete ballasting until the vessel is in deeper water to avoid further sediment uptake. These BMPs assume that sediment concentrations are higher nearer the lake bottom than they are at the top of the water column.

1.2 Objectives and Scope

The primary objective of this sampling program is to collect primary data that will be used to:

[1] "Laker" is the common name for the large and uniquely designed and constructed dry bulk vessels (or carriers) used to transport bulk material commodities throughout the Great Lakes system. U. S. flag Lakers usually only transport goods on the four upper Great Lakes and connecting channels, as *most* are limited by their size from transiting the Welland Canal. The primary commodities transported by the Lakers include iron ore pellets, coal, grain, limestone, cement, sand, and salt.

- Determine if water collected from lower in the water column has a higher concentration of sediment than water collected from higher in the water column;

- Determine whether the suction created by the ballast pumps on Lakers increases sediment intake; and

- Determine if the amount of sediment transferred into ballast tanks on Lakers would decrease if vessels collected ballast water from higher in the water column (e.g., by using side or upper sea chests) rather than close to the lake bottom (e.g., by using bottom or lower sea chests).

2. PORT LOCATION SELECTION

In general, EPA will select for sampling a port in the Great Lakes where cargo is off-loaded and ballast water loaded, and where a variety of Laker types frequent. The port should also be operated by a public entity such as a port authority rather than a privately-owned port which will limit access by EPA. In addition, the ambient water turbidity of ports located on lakes will have less interference from rain runoff than from ports located in a river. Therefore the port selected for sampling should be an open-water Great Lakes port and not a river port on the Great Lakes. The water depth adjacent to the docks should be at least 28 feet to accommodate a fully ballasted 1,000-foot Laker having a draft of 27.8 feet (aft).

To select an appropriate port for sampling, ERG summarized the characteristics on the top 10 ballast water loading ports on the Great Lakes (USCG, 2013). The top 10 ballast water loading ports along with port characteristics are provided in Table 2-1.

Table 2-1. Characteristics of the Top 9 Great Lakes Ballast Water Loading Ports

United States Great Lakes Port	Annual Ballast Water Loaded (mt/yr)[a]	Port Type	Port Operating Responsibility[b]	Vessel Types Entering Port[c]
Gary	4,534,821	Harbor	United States Steel and Leigh Portland Cement	1,000' Lakers and Intermediate Lakers
Indian Harbor	3,742,141	River	U.S. Army Corp of Engineers	1,000' Lakers and Intermediate Lakers, River Class Lakers
Saint Clair River and Port Huron	3,313,204	River	Port Huron Maritime Commission	River Class Lakers
Monroe	3,119,239	River	Monroe Port Commission	Intermediate Lakers and River Class Lakers
Cleveland	2,662,340	Harbor	Cleveland and Cuyahoga County Port Authority	1,000' Lakers and Intermediate Lakers
Burns Harbor	2,487,640	Harbor	Ports of Indiana Port Authority (State of Indiana)	1,000' Lakers and Intermediate Lakers
Detroit	2,283,156	River	Detroit and Wayne County Port Authority	1,000' Lakers and Intermediate Lakers
Conneaut	1,810,050	River	Canadian National Railroad	1,000' Lakers and Intermediate Lakers
Ashtabula	1,511,532	Harbor	Ashtabula City Port Authority	1,000' Lakers and Intermediate Lakers

[a] USCG, 2013.

[b] World Port Source and www.worldportsource.com.

[c] Estimated based on docking or berthing lengths provided on the port websites.

Based on the information in Table 2-1, the ports at Astabula, Burns Harbor, and Cleveland are the top candidates for sampling. The final decision on which single port will be sampled will be based on sampling team and laboratory logistics.

3. SAMPLE COLLECTION METHODS

This section describes the sampling procedures and associated analytical methods the sampling crew will use to determine if sediment concentrations change with depth at ballast water loading ports, and if pumping of ballast water increases sediment loadings.

3.1 Sampling Approach

The sampling crew will collect samples at various depths from water adjacent to a pier at which Lakers may operate. However, the sampling crew will select locations along the pier that have not seen recent Laker activities such as ballasting and deballasting to eliminate this potential source of sampling variability. The crew will use two separate techniques performed sequentially. Using the first technique, the sampling crew will collect discrete grab samples of the water column using a Kemmerer sampler to determine the concentrations of suspended solids, organic carbon, and turbidity. The crew will collect samples at approximately 5-foot increments beginning approximately 8 feet below the surface and ending near the harbor bottom. Based on anticipated harbor depths ranging between 28 feet and 30 feet, ERG expects to collect samples at 5 depths from each sampling location. Figure 3-1 shows where and what type of samples will be collected at various locations and depths along the pier. This first sampling technique is intended to collect water column samples relatively quiescently, with minimal suspension of sediment from the lake/river bottom. The second technique will employ a portable pumping system having a similar intake velocity as a Laker ballast water pumping system. Using the pump, the sampling crew will collect samples at the same depths as those collected using the Kemmerer sampler, and these samples will also be analyzed for suspended solids, organic carbon, and turbidity. This second technique is intended to simulate ballasting by a vessel. The sampling crew will tether the pump hose to either a weight or stiff pipe to prevent the hose from moving within the water column, and to keep the hose at the desired depths. In addition, both sampling apparatuses will be deployed from a pulley system that will extend the sampling equipment about 3 feet away from the pier to minimize any influence by the pier.

A total of 3 replicates sample sets will be collected. A sample set consists of the samples collected at a specific location on the pier at each of the series of specified depths by both the Kemmerer sampler and the pump. Following completion of a sample set, the sampling equipment will be moved to a new location on the pier and another sample set completed. Sample sets will be separated by a minimum of 60 feet to prevent sediment which may have been re-suspended during collection of the previous sample set from impacting the subsequent sample sets.

The sample results from the Kemmerer sampler and the portable pump will then be compared to determine the effect of the pump on sediment entrainment and loading. The following subsections provide details on the use of the Kemmerer sampler and pump for collection of samples from the water column.

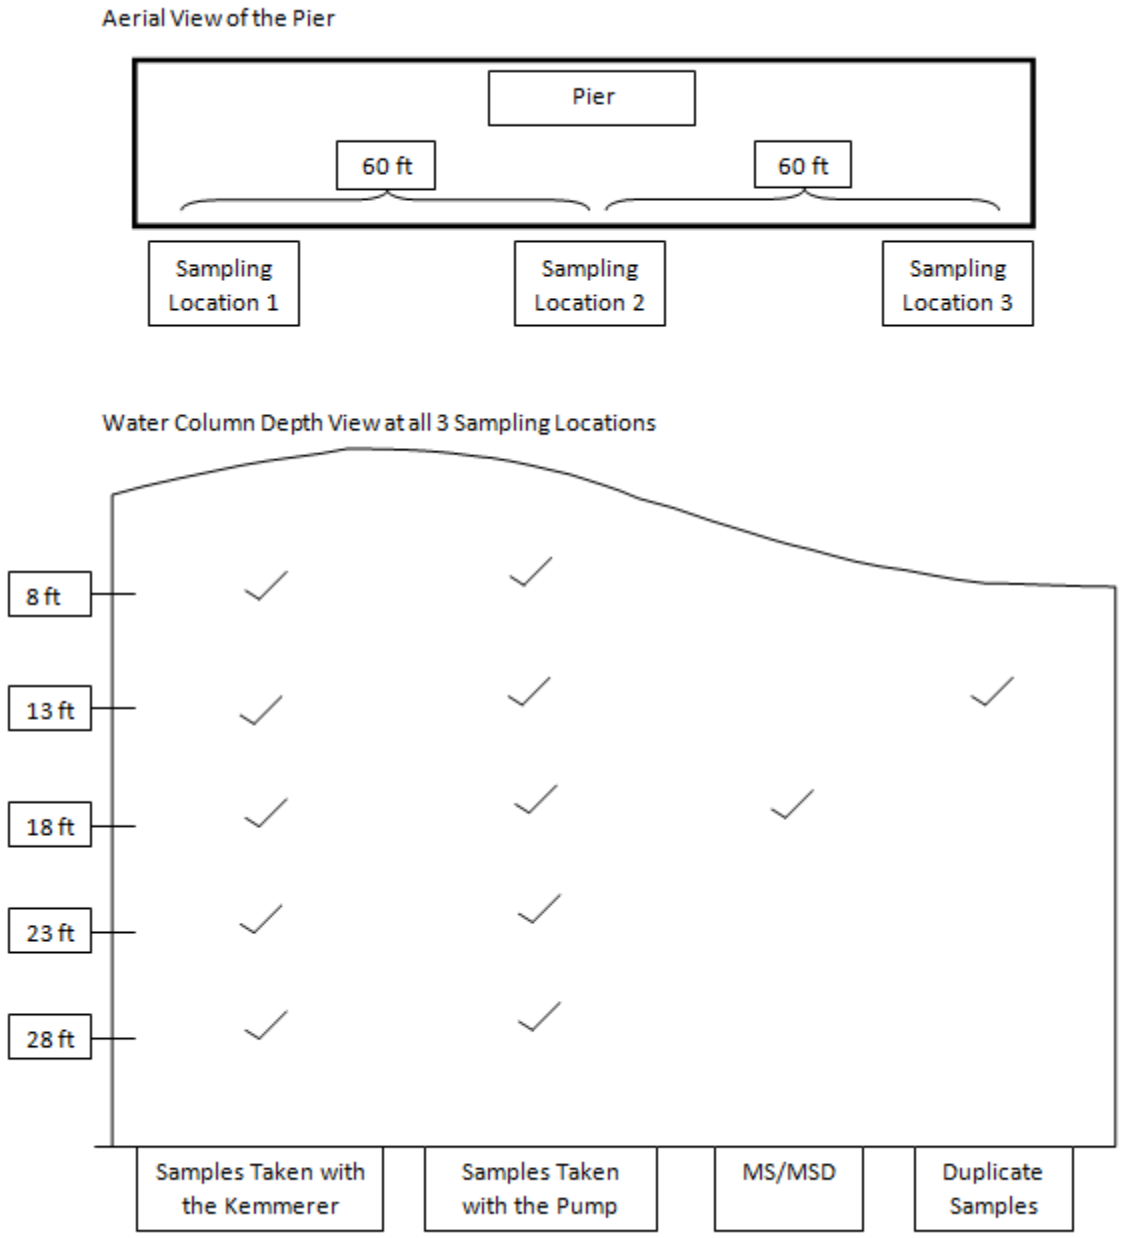

Figure 3-1. Sampling Diagram

3.1.1 Kemmerer Sample Collection

Samplers will use a 1.2-liter Kemmerer sampler to collect samples at various depths (see Figure 3-2 and Appendix A for manufacturer instructions). The rope attached to the Kemmerer sampler will be pre-measured with 6-inch increments and the Kemmerer will be lowered to the desired depth. Once the Kemmerer sampler reaches the desired depth, the unit will be closed, the collected water sample will be brought to the surface, and the collected sample will drained into

the appropriate sample bottles. The process will be repeated at each target depth until all planned samples have been collected.

Figure 3-2. Kemmerer Sampler

3.1.2 Pump Sample Collection

The sampling pump used to simulate a Laker ballast pump will be a Honda WB20X (or equivalent) fitted with a 2-inch diameter flexible intake hose lowered in the water column to the same depths as the Kemmerer sampler. Using information provided in the literature, ballast pumping rates on board Lakers averages 36.7 gpm/in^2. Therefore, the pumping rate on the portable pump will be set to 115 gpm which provides a rate of approximately 36.7 gpm/in^2 through the 2" suction hose. The pump will be calibrated at the sampling location to 115 gpm prior to the sampling event. Prior to sample collection at each location and depth, the pump hoses will be flushed with ambient water for at least 1 minute to remove any residuals from the previous sampling location. Effluent from the pump's discharge line during line flushing and sampling will be directed away from the sampling area to avoid sediment disturbance.

Because of the high pump flow rate, the pump discharge hose cannot be used to fill the sample bottles. Instead, the pump discharge will be directed into a clean 5-gallon plastic pail, and then the pail will be used to fill the individual sample bottles. The pail will be manually shaken and swirled during filling of the sample jars to prevent solids from settling.

3.2 Analyte Selection

To determine sediment concentrations, ERG will contract for laboratory analysis for total suspended solids (TSS) and particulate organic carbon (POC). The sampling crew will measure turbidity in the field. Table 3-1 lists the analytes, laboratory methods, and their detection limits.

Table 3-1. Analytical Methods and Detection Limits for Sampled Analytes

Analyte	Method Number	MRL	Units
Total Suspended Solids (TSS)	SM 2540 D	3	mg/L
Particulate Organic Carbon (POC)	UWM-LECO	1	mg/L
Turbidity	SM 2130 B	0.05	NTU

MRL = Method Reporting Limit.

3.3 Sample Fractions, Bottle Sets and Sampling Collection

ERG will split samples collected by each technique at each depth into bottles designated for TSS and POC analysis. Separate bottles will be used for TSS and POC since a total of 3 liters is needed for analysis and the laboratory has an inventory of 1-liter bottles on hand. Table 3-2 lists the estimated number of samples, sample bottles, sample volume, preservation method, and sample holding time for each type of analysis. In addition, quality assurance/quality control samples will be collected. These include duplicate samples collected at a rate of 10 percent for each analyte, and extra sample volumes collected at a rate of 10 percent for laboratory matrix spike and matrix spike duplicate (MS/MSD) analyses of POC. Extra volume MS/MSD analysis will include two additional 1 liter plastic bottles for each set of matrix spike and matrix spike duplicates.

The sampling crew will pack samples in ice chests with a sufficient quantity of wet ice to maintain a temperature of ≤6°C until the samples can be packaged and transferred to the analytical laboratory. Each package delivered to the laboratory will contain a temperature blank and the temperature will be taken and noted on the Chain of Custody report at the time of shipping. The temperature of the temperature blank will also be recorded by the laboratory upon receipt of samples.

Table 3-2. Summary Number of Samples, Sample Bottles, Preservation, and Holding Time Requirements

Parameter	Estimated Number of Samples[b,c,d]	Sample Bottle and Volume	Preservation	Holding Time
TSS	35	1 1-L Plastic Bottle	Cool, ≤6°C	7 days
POC	38	2 1-L Plastic Bottles	Cool, ≤6°C	7 days
Turbidity[a]	35	NA	NA	NA

[a] Measured in the field.

[b] Includes additional duplicate samples collected at a rate of 10 percent for TSS, POC, and turbidity.

[c] Includes extra volume collected for POC at a rate of 10 percent for (MS/MSD) analysis.

[d] Includes an equipment blank from both the Kemmerer sampler and the pumping system for TSS, POC, and turbidity.

3.4 Sample Labeling

Each sample bottle will be coded with a unique sample number and labeled at the time of collection. The self-adhesive label will be completed in indelible ink and will contain the following information:

- Sample number;
- Sampling location;
- Sampling point description;
- Analysis to be performed;
- Sample bottle type;
- Date of sample collection; and
- Preservation used.

Once applied to the sample bottle, labels will be covered with clear tape to prevent tampering, abrasion, smearing, or loss during transit.

3.5 Chain of Custody

To maintain a record of sample collection, shipment, and receipt by the laboratory, a Chain of Custody Report (CCR) will be filled out listing the samples bottles contained in each ice chest transferred to the laboratory. These forms will be completed and used to document sample custody transfer from the field to the laboratory. At the time of sample transfer, a copy of the CCR will be retained by ERG and the remainder of the copies will be transmitted with the samples to the analytical laboratories. The analytical laboratory will send a copy of the CCR to ERG to acknowledge receipt and the condition of the samples. To verify the coolers containing the samples have not been opened during shipment to the laboratory, a custody seal will be placed on each cooler at the time of shipment.

4. QUALITY ASSURANCE FOR ANALYTICAL LABORATORIES

ERG will contract with a commercial laboratory to analyze samples for TSS and POC. Contacts for the laboratory performing these analyses are provided below in Section 5.4.4. Quality assurance/quality control (QA/QC) procedures applicable to this sampling program are outlined in the QAPP (USEPA, 2014). The QA/QC program includes the components discussed in the following subsections.

4.1 Documentation of Sample Custody

While samples are being collected, samples and sampling equipment will be maintained in the physical possession or view of at least one member of the sampling crew, or kept inside a locked cooler. To maintain a record of sample custody, the sampling crew will complete a CCR form for each cooler that is transferred to the laboratory. Custody seals will be used to ensure secure sample transfer between personnel and sample receipt by the laboratory. These CCR forms will be used to document sample custody transfer from the field to the laboratory and will contain the following information:

- Sample number for each sample in shipment;
- Collection date and time for each sample in shipment;
- Preservation for each sample in shipment; and
- Sample description (environmental matrix).

4.2 Field Duplicate

The sampling crew will simultaneously collect field duplicate samples by collecting twice the volume as a normal sample from the same location to evaluate total measurement precision and cover all the sources of data variability, including sample collection, handling, preparation, and analysis. Field duplicates will be collected at a frequency of one per batch of 10 samples (10 percent).

4.3 Equipment Blank

Equipment blanks will be collected and analyzed for any sampling equipment, other than sample bottles, that come into direct contact with samples. Anticipated sampling equipment for which equipment black will be prepared include: 1) the Kemmerer sampler, and 2) the pumping system including the pump, hoses, and collection pail. Equipment blanks will be analyzed for the same parameters that are analyzed on the samples collected using the sampling equipment. The sampling crew will collect equipment blanks by rinsing sampling equipment with tap water to verify the non-contaminated condition of sampling equipment. Tap water is not expected to contain measurable TSS, POC, or turbidity and therefore is adequate for use in preparing equipment blanks. Equipment blanks will be collected at a frequency of one per type of sample collection equipment used.

4.4 Matrix Spikes/Matrix Spike Duplicates

Additional sample volumes will be collected for POC when MS/MSD testing is required. The same volume collected for a POC sample will be sent to the laboratory as the MS/MSD for every 10 samples (10 percent) submitted for analysis.

5. SAMPLING ACTIVITIES

This section of the sampling plan summarizes the sampling team organization, pre-visit Preparation, field sampling activities, and logistics such as, port contacts, and analytical laboratory contacts and addresses.

5.1 Sampling Team Organization

The sampling crew will consist of a two to three person team, depending on location and anticipated sampling effort. The crew chief will be responsible for all sample collection, preservation, and shipping activities while on-site. The sampling crew will compile and collate the analytical results.

5.2 Pre-Visit Preparation

Prior to the sampling event, the crew chief will distribute the SAP, QAPP, and health and safety plans to each team member and ensure they are completely familiar with the sampling, quality, and health and safety requirements. The crew chief will also provide site personnel copies of the SAP and any site-specific supplemental information prior to the start of sampling.

The crew chief will also coordinate the procurement and shipment of all necessary sampling and health and safety equipment.

5.3 Field Sampling Activities

The crew chief, in conjunction with the EPA Representative (if available) will meet with site personnel to determine whether samples can be collected at each of the planned sampling locations. Upon making the decision to collect samples, the crew chief will update the descriptions of the proposed sampling locations, if necessary, in consultation with EPA. If necessary, additional equipment will be obtained. The revised description will include:

- A sampling location description and collection procedure for each sampling location;
- A list of the sample fractions to be collected:
- A list of potential physical hazards (such as pH, temperature, and potentially hazardous equipment);
- A list of any potential chemical hazards associated with each sampling location; and
- A list of proposed health and safety procedures.

Prior to sampling, the crew chief will also notify ERG's Health and Safety Coordinator of any revised sampling activities along with recommended revisions to the proposed health and safety procedures. Together, they will review the proposed health and safety procedures,

incorporate any site-specific changes indicated by the Health and Safety Coordinator, and obtain approval for sampling from the Health and Safety Coordinator before proceeding with sampling activities.

Sample fractions collected will be labeled, sealed, packaged, and placed in coolers with ice for shipment to the laboratory. The CCR will be completed and placed in plastic sleeves inside the coolers, and a custody seal placed over each cooler. The coolers will then be transferred to the designated laboratory. At the conclusion of the sampling event, the sampling equipment will be prepared for return shipping.

The crew chief will contact the laboratories prior to transporting the samples to communicate the number of samples collected. The crew chief will also contact the laboratories after shipping samples to communicate shipping information and verify sample receipt.

5.4 Logistics

This subsection summarizes the sampling team personnel, port contacts, analytical laboratories, EPA contact and address, and ERG project management contact and address.

5.4.1 Sampling Team

Mark Briggs (Crew Chief)
ERG
3400 Jack Morris Drive
West Branch, MI 48661
Office: (989) 345-7595
Cell: (989) 701-5850
mark.briggs@erg.com

Kathleen Wu
ERG
14555 Avion Parkway, Suite 200
Chantilly, VA 20151
Office: (703) 633-1625
Cell: (703) 581-7390
kathleen.wu@erg.com

5.4.2 Port Contacts

To be determined prior to sampling.

5.4.3 EPA Contacts

Dr. Ryan Albert
Mail Code: 4203M
1200 Pennsylvania Ave., NW
Washington DC 20460
(202) 564-0763

albert.ryan@epa.gov

(703) 633-1607
debra.falatko@erg.com

5.4.6 Freight Forwarders

Federal Express (FedEx)
General Information (800) 238-5355

Location of specific shipping options to be determined.

6. SAMPLE HANDLING AND SHIPMENT

If logistics between the sampled port and the laboratory are reasonable, ERG will drive the samples to the laboratory rather than shipping via FedEx or using a courier service. If samples are driven to the laboratory, they will be placed in ice chests on wet ice and the ice chests will remain in the locked vehicle until arrival at the laboratory. Each ice chest will include a Chain of Custody Report with information on the samples held within. At the laboratory, ERG will transfer custody of the samples to laboratory personnel.

If the sampling port logistics do not allow ERG to drive the samples to the laboratory or to use a courier service to the laboratory, then samples will be packaged for shipment via FedEx. The following subsections outline the sample packing procedures that will be used if samples are shipped to the laboratory via FedEx.

6.1 Sample Packing

All samples will be packed according to the following guidelines:

1. Tighten the lid on each filled sample bottle, being careful not to over-tighten the lid. Clean the sample bottle with a cloth rag or paper towel.

2. Package sample bottles into individual sealable plastic freezer bags.

3. Place two garbage bags inside each other in a cooler.

4. Place packaged sample bottles and a temperature blank in garbage bags in the cooler with proper end up and close bag with twist-tie.

5. Arrange sealed plastic freezer bags filled with ice (or chemical ice) on top of the sample bottles. Put at least 4 × ½ gallons of ice (4 × 2.5 lbs of ice) in each large cooler and 2 × ½ gallons of ice (2 × 2.5 lbs of ice) in each small cooler. More ice should be used when ambient temperatures are very high. The ice should be placed inside the second garbage bag. Close the second garbage bag with a twist-tie. Any additional free space should be filled with packing material so that the sample bottles will not shift during shipment.

6. Seal the Chain of Custody Report form in a plastic sleeve and tape securely to the inside of the cooler lid.

7. Place a "Return to ..." label on the inside of the cooler lid.

8. Close cooler.

9. Make several wraps with strapping tape around the cooler perpendicular to the seal to ensure that the lid will remain closed if the latch is accidentally released or damaged.

10. Tape the cooler drain plug so it will not open.

11. Place a completed address label on the lid of the cooler including name, address, and telephone number of the receiving laboratory and the return address and telephone number of the shipper.

12. Place a custody seal on the cooler in a manner that will allow the laboratory to verify the cooler has not been opened during shipment. Place clear tape over the custody seal to ensure the custody seal will remain on the cooler during transport to the laboratory.

6.2 Sample Shipping

All sample packages will be labeled with self adhesive labels as described in Section 3.4. All samples will be tracked using CCR forms. Custody will be maintained by the crew chief from sample collection through shipment.

All samples will be packaged and shipped in accordance with Department of Transportation (DOT) or International Air Transport Association (IATA) regulations. The general IATA packaging requirements for air shipment are as follows:

- Inner packaging must be so packed, secured or cushioned as to prevent their breakage or leakage and so as to control their movement within the outer packaging during normal conditions of transport. Cushioning material must not react dangerously with the contents of the inner packaging. Any leakage of the contents must not substantially impair the protective properties of the cushioning material. Unless otherwise provided in this paragraph or in the Packing Instructions, liquids in Classes, 3, 4, 5, 6, or 8 of Packing Groups I or II in glass or earthenware inner packaging, must be packaged using material capable of absorbing the liquid. Absorbent material must not react dangerously with the liquid. (IATA Dangerous Goods Regulations, 5.0.16).

- "When filling receptacles for liquids, sufficient volume (outage) must be left to ensure that neither leakage nor permanent distortion of the receptacle will occur as a result of an expansion of the liquid caused by temperatures likely to prevail during transport. Liquids must not completely fill a receptacle at a temperature of 55°C (130°F)." (IATA Dangerous Goods Regulations, 5.0.12).

EPA does not anticipate that samples collected from ports will be classified as IATA dangerous goods, and therefore shipping requirements for dangerous goods have not been included in this sampling plan. If dangerous goods shipping does occur during the course of this sampling program, then the sampling team crew chief will consult with a dangerous goods shipping contact located in ERG's office in Chantilly, Virginia, and appropriate hazardous shipping procedures will be followed.

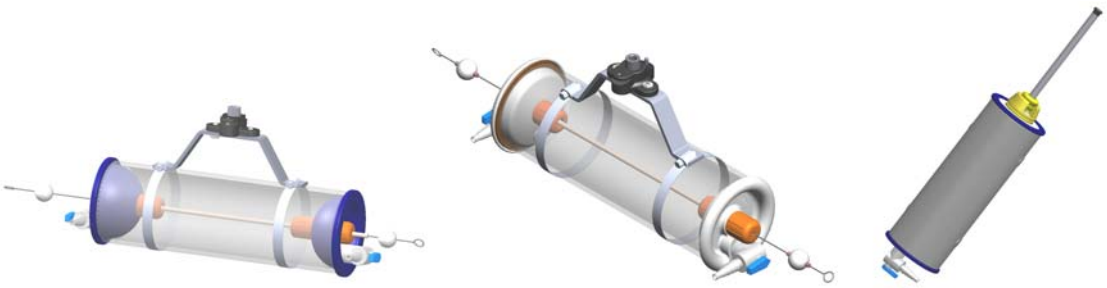
EXCERPTS FROM A COMPREHENSIVE GUIDE TO WILDCO® WATER BOTTLE SAMPLERS

Wildlife Supply Company®



A Comprehensive Guide to Wildco® Water Bottle Samplers

Table of Contents:

INTRODUCTION TO WILDCO

Wildlife Supply Company was established in 1938 by the Trippensee brothers, Dr. Rueben and Herbert. Dr. Rueben was a professor at the University of Massachusetts for 30 years. His two published texts on wildlife management have long served as references in their field. The company remained in the Trippensee family for over 60 years.

The company changed hands in 2000, when it was purchased by the Bell family.

Wildco has always been a family business, whether the family is the Trippensees or the Bells. Because of this, the owners think long term. You can count on sturdy, reliable products that give you the ability to compare your samples to data of past decades.

INTRODUCTION TO WATER SAMPLE BOTTLES:

Wildco water sample bottles are designed for grabbing a sample of water at a known depth. This is why they are referred to as *in situ* water samplers or discrete depth water samplers.

These sampling devices are Messenger operated. They are lowered into a body of water in the open position. When the bottle reaches a desired depth, a weight, or Messenger, is slid down the line until it hits a trigger device on the bottle, known as a trip head. This causes the bottle to close.

Wildco Messenger

Alpha and Beta bottles are available with either transparent acrylic or opaque PVC bodies. They can be either vertical or horizontal with relation to the substrate. Kemmerer bottles are vertical and can have transparent acrylic, opaque PVC, stainless steel or PTFE bodies. Van Dorn style bottles can be horizontal or vertical. Both types of bottles serve the same function, but they have different trip heads and end seals.

All bottles are available in a kit, containing the bottle, line, a messenger, and carry case.

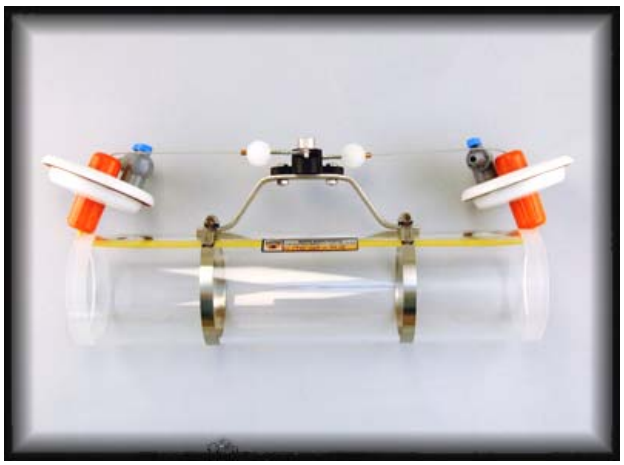
HOW TO CHOOSE THE RIGHT BOTTLE:

Van Dorn style sample bottles are well suited for general purpose sampling at any depth. Available with clear acrylic or opaque PVC bodies, they can be had in both **horizontal and vertical** configurations, with relation to the substrate. **Vertical** bottles allow a free flow of water through the bottle as it moves down the water column. **Horizontal** bottles tend to fill at the surface and should be tugged sideways at the desired depth to obtain a good sample. For both style of bottles, the end seals are off to the side of the bottle body when set open.

Two types of the Horizontal and Vertical Van Dorn style bottles are available:
Alpha bottles are best for general purpose sampling. The Alpha bottle is very sturdy, but is unsuitable for chemical sampling.

Horizontal Alpha Bottle

Beta style bottles are ideal for trace metals and chemical sampling.



Horizontal Beta Bottle

Kemmerer bottles come in a variety of configurations for specialized sampling. They are vertical only. They have fewer working parts than the Van Dorn style. The Kemmerer design assures flushing of the bottle as it descends through the water, and it closes with much less agitation and disturbance. Kemmerer bodies are available in acrylic, PVC, stainless steel, and PTFE. The end seals are in line with the bottle body when set open.

Kemmerer Bottle

Representative example situations:
Below are some common sampling situations and suggestions for appropriate samplers.

Plankton – The wide mouth of the Alpha and Beta bottles allows little restriction of flow through the bottle as it moves down the water column. Therefore, they are preferred for sampling standing crops, primary productivity and other quantitative measures, because they allow free water flow throughout the bottle. Because they collect whole water samples, all size classes of plankton are obtained. They are sometimes used for sampling nanoplankton and picoplankton, which can pass through most nets due to their extremely small size. The larger bottles, 6.2 or 8.2 liter, are good for this purpose.

For larger types of plankton, Wildco makes a variety of high quality plankton nets as well as the Schindler-Patalas Plankton Trap, which combines a large sampling box with a net for filtering out the plankton.

Trace Organics – Most water sampling bottles are made with plastics, and are generally unsuitable for trace organic sampling. Wildco® makes two Kemmerer bottles which are suitable: 1295-B32 is all Teflon, while 1200-G32 has a stainless steel body with Teflon seals. Since there is a possibility of contaminants in the bottle, **Wildco® recommends running a blank to get a baseline before doing organic sampling.**

Trace Metals, Metallic Ion Avoidance – Beta bottles, all plastic Kemmerer bottles with silicone seals, and the all PTFE Kemmerer bottle are recommended. The blue polyurethane end seals on the Alpha bottles and some Kemmerer bottles may leach mercury into the water, at concentrations of 20-450 ng/L. They may also leach

phosphorus and other chemicals in small amounts. Since there is a possibility of contaminants in the bottle, Wildco® recommends to run a blank to get a baseline before doing trace metal sampling.

Large Volume – If a larger volume of water is needed in one haul, several options are available. Alpha and Beta bottles come in 6.2 and 8.2 liter sizes, the 1260-E32 and1560 series Kemmerer bottles hold 6.2 liters and the 1580 series Kemmerer bottles hold 8.2L. For plankton, the 12 liter or 30 liter Schindler Patalas trap can be used.

Wells – The Kemmerer Well sampler is long and thin and fits easily into a 2-inch pipe. It can sample at any depth. 1280-A12 has polyurethane seals, and 1280-B22 has silicone seals. A 45-B40 messenger shock absorber may be needed, as it will help to protect the trip mechanism if there is a long air drop before the messenger reaches the bottle.

Narrow Opening – In this case defined as a hole in ice, drum sampling, or confined space sampling. The Kemmerer well sampler is ideal for this, fitting into a two inch pipe. The Teflon Kemmerer has a 2-7/8" outside diameter, and the 0.4 and 1.2 liter versions of the stainless steel Kemmerer have 2-5/8" outside diameters. A 45-B40 messenger shock absorber may be needed, as it will help to protect the trip mechanism if there is a long air drop before the messenger reaches the bottle.

Thermocline/Stratified Lakes – horizontal Alpha and Beta bottles are mostly used for discrete point sampling at a given depth, which makes them ideal for sampling the water column in a stratified lake. Lakes often develop a layer of warm water on top of cold water, due to the fact that warm water is less dense than cold. In large bodies of water, the layer between these regions can be very distinct. This area, called the thermocline, can be very narrow, with the temperature changing rapidly with depth. The lake environment is very different above and below the thermocline. A horizontal bottle can get fairly accurate samples above, below and right at the area where the water mixes.

Series – This is sampling at multiple depths. To sample with multiple bottles on one line, Wildco makes the Series Sampling Bottle. Up to five of these Beta style bottles can be placed on the same line, each with a messenger above its trip. After a messenger is dropped on the top bottle, all the bottles will close in rapid succession.

Severe Environment – Sampling environments such as industrial solvents, strong acids and bases, corrosive chemicals, and temperatures up to 440 degrees. Wildco® makes two Kemmerer bottles suitable for this purpose: 1295-B32 is all Teflon, and 1200-G32 has a stainless steel body with Teflon seals.

Need a sterile bottle? Autoclaving is the best way to sterilize a sampler. Wildco® makes two bottles which can be autoclaved: 1295-B32 is all Teflon, and 1200-G32 has a stainless steel body with Teflon seals.

Shallow Water – Horizontal Alpha and Beta bottles are mostly used for discrete point sampling at a given depth, and are the best for very shallow water. For long air drops, consider using a 45-B40 messenger shock absorber to help protect the trip head.

Just Above the Substrate – Horizontal Alpha and Beta bottles are often used for this purpose. The tube itself lies parallel to the lake bed, allowing for close up sampling.

Composite Samples – Samples can be taken with the same bottle at different depths and the contents combined, or samples can be pooled from the same depth.

Water Temperature at the Time of Sampling - A thermometer can be mounted on the inside of most clear acrylic Van Dorn or Kemmerer Bottles. This is done at the factory before shipping. The bottle should be left at the desired depth long enough for the thermometer to stabilize. When the sample is retrieved, the reading should be taken immediately for better accuracy.

Rough Conditions - The 2.2 Liter PVC Alpha Bottle (1120-H42) is very sturdy and the least likely to break. The PVC Beta Bottles are slightly less sturdy than the Alpha due to their silicone gasket. Kemmerer bottles tend to be more delicate. Care should be taken to avoid problems such as hitting a rock or the side of a boat with any bottle. The trigger mechanisms on the bottles are, by design, very sensitive and may trip early if they hit the surface of the water too hard. Acrylic bottles afford a view of the contents, but may shatter if dropped on one end.

Opaque vs. Transparent - Clear acrylic bottles allow a full view of the contents during your fieldwork, but chemical changes and effects on plankton may occur when exposed to sunlight. Opaque bottles prevent sunlight from affecting the sample. The opaque bottles are made from PVC, which tends to be cheaper and more crack resistant than acrylic.

TIPS FOR TRACE METAL SAMPLING

1. All samplers contaminate or distort in some way.
    - Plastics may leach metals from ultraviolet inhibitors, metal-organic plasticizers, and (rarely) metal catalysts.
    - PTFE has a rough porous surface that traps ions and fine charged particles. Errors may occur in your first sample.
    - Metal and glass may dissolve into the sample, usually at the nanogram/ liter level.
    - Sample may react with the sampler, causing errors.

2. Are you using the right sampler? Is the sampler clean? Have you run a test blank?

3. Selecting a particular sampler may depend upon the material(s) sought or environment being sampled.

4. Alconox is suggested to remove oil and most soils. Rinse. A 3% acid solution (HCl or HNO_3) will remove detergent. Rinse with distilled water. Air dry.

5. Run a test blank by filling the sampler with distilled water, holding for at least as long as the sample will be held in the sampler, and running test analysis.

NOTES ABOUT CONTAMINATION:

Blue end seals may leach small amounts of mercury and phosphorus, and thus are not recommended for chemical sampling. Make sure you have the right bottle, one with silicone seals.
Avoid cross contamination by thoroughly cleaning your equipment after each use.

TEST BEFORE YOU SAMPLE:

We recommend that any new sampler be thoroughly cleaned prior to any sampling.
If you are performing metal or chemical sampling, run a blank before using the bottle. Fill the instrument with distilled, contaminant free water, and test to determine what contaminants may be present in the sample.

We also recommend that this procedure be repeated throughout the sampling season.

PREPARING WATER SAMPLERS FOR USE

1. General cleaning
   a. For most sampling, soak in mild detergent and warm water (to 150° F/ 65° C). Rinse with tap, then distilled water.
   b. Soak in mild laboratory detergent such as Alconox and warm water. Rinse with distilled water, rinse again with 3% HCl or HNO_3, then with triple distilled water. Repeat. Store when completely dry in clean, sealed plastic bag.

2. Trace level decontamination for plastic samplers
   a. Clean as above, then soak up to 8 hours in warm 1N HCl solution (3 N maximum), then rinse in distilled water. **Do not use alcohol, ketones or chloroform on acrylic**.

3. Removing grease and oils
   a. Wash with mild detergent to remove grease and oil. **Do not use solvents on acrylic.** Use **alcohol only** on Lexan, PVC and CPVC.

4. Sterilizing samplers
   a. Autoclaving: Clean and rinse with distilled water before autoclaving to prevent baking contaminants.
   b. Metal, glass, Teflon™, polycarbonate may be autoclaved. **Do not** autoclave polyurethane, PVC, CPVC, acrylic, CAB.
   c. Gas sterilization: The above materials can be gas sterilized using formaldehyde gas or ethylene oxide.
   d. Chemical sterilization: In general all the above can be sterilized with commonly used disinfectants.

5. Trace metal or organic measurements
   a. Fill sampler with distilled water for same length of time you would fill with sample. Analyze the distilled water.

6. Rust stains on stainless steel
   a. *All stainless steel devices should be rinsed at once with fresh water* after removal from salt water.
   b. To remove rust, soak in concentrated HNO_3 for 3-4 hours.

7. Storage of samplers
   a. To avoid mildew, corrosion, and odors, samplers should not be stored in foam-lined cases unless very dry.

PERSONAL SAFETY:

The trigger mechanisms on bottles of this type are very sensitive by design. To prevent injury, keep your hands clear of the main tube when the bottle is in the open position. The end seals close with surprising force. **Do not operate out of water!**

BOTTLE SAFETY AND CARE:

Wildco recommends an 11 ounce messenger (such as 45-B10), unless there is a very long air drop and the bottle is close to the surface of the water, in which case a lighter messenger may be used. Under these conditions, a messenger shock absorber (45-B40) may also be used to help protect the trip mechanism. Do not use a messenger heavier than 11 ounces, as this may damage the trip mechanism.
Perform a preliminary inspection prior to using the bottle. Make sure the line and cable are tightly connected.

Guard the sampler from blows to the cylinder ends. This may knock them out of round, which could cause leakage during sampling. Dropping or impacting the sampler can crack the main tube. A blow to an acrylic body can cause it to crack or shatter.
Always lower the bottle slowly, without dropping it.
To avoid damage during use, the sampler should always be transported in a carry case.

MAINTENANCE AND CLEANING:

Storing bottles with the valves closed may cause them to "set" tightly in the end of the bottle, resulting in damage when pried open. Store the bottle so the end seals do not touch the cylinder.
After sampling, rinse the sampler in fresh, clean water. Allow the sampler and case to completely dry.
Do not store the sampler when wet, damp, or dirty. This can cause mold, mildew, metal corrosion, or plastic surface deterioration.
The foam interior of the case may deteriorate or be damaged if the product is not dried after use.
When fully dry, store the sampler in its case, or in a dark, cool shelf or cabinet.

RECOMMENDED ACCESSORIES:

3001-B15 Thermometer.
3001-A10 Thermometer mount.
62-C15 3/16" Polyester line, 100ft.
61-B14 1/8" diameter steel Aircraft Cable, 100ft.
45-B10 Split Messenger, 11 ounce.
45-B40 Messenger Shock Absorber.
66-A50 Hand Winding Reel.
Plastic Carry Case.

QUALIFIER	DESCRIPTION
J	Estimated value
MD01	The laboratory duplicate RPD for this sample exceeded the control limit.
MD02	The laboratory duplicate RPD for this sample exceeded the control limit. Since the initial and/or the duplicate sample result was less than 5 times the reporting limit, the initial reported sample result is not qualified.
U	Analyte included in the analysis, but not detected

SDG CASE NARRATIVE

Eastern Research Group
Burns Harbor

SDG Executive Summary

This case narrative applies to samples received on May 29, 2014. All samples were scheduled for analysis in accordance with parameters outlined on the field chain of custody record, the TriMatrix bid form, and/or oral and written correspondence between Eastern Research Group and TriMatrix Laboratories, Inc.

Each sample receipt event was assigned a unique TriMatrix work order number. Sample receipt documentation is included in section A of this data package.

Project Technical Issues/Problems

Project-related data qualification designations, narrations, and reporting conventions are included in Attachment 1 - *Project Technical Narrative(s)*.

QA/QC Data Qualifications/Narrations

Quality assurance issues and/or quality control data qualifications and narrations related to the analysis and reporting of this SDG are presented in Attachment 2 - *Statement of Data Qualifications*. The absence of a statement page for a particular analyte group (*e.g.* Percent Solids) implies that no qualifying statements were generated for that analyte.

Data Review and Approval

All data was peer-reviewed by a second analyst, and then by appropriate data management staff against laboratory quality control requirements and project specifications. It was then reviewed and approved by the group supervisor/manager prior to further review by the project chemist.

Data Deliverables

This report relates only to the sample(s) as received. Estimates of analytical uncertainties for the test results contained within the report are available upon request. Test results are in compliance with the requirements of the National Environmental Laboratory Accreditation Conference (NELAC), and one or more of the following certification programs:

ACLASS DoD-ELAP/ISO17025 (#ADE-1542); Arkansas DEP (#13-049-0); Florida DEP (#E87622-24); Georgia EPD (#E87622-24); Illinois DEP (#003329); Kansas DPH (#E-10302); Kentucky DEP (#0021); Louisiana DEP (#103068); Michigan DPH (#0034); Minnesota DPH (#367345); New York ELAP (#46503); North Carolina DNRE (#659); Texas CEQ (#T104704495-14-4); Virginia DCLS (#2592); Wisconsin DNR (#999472650); USDA Soil Import Permit (#P330-09-00163).

SDG CASE NARRATIVE

The data deliverables, both hardcopy and/or electronic (EDD), that comprise this data package are intended to comply with the documents referenced in the introductory section of this narrative. The EDD, if requested, will be issued separately from this hardcopy report. Hold time reports for each test procedure are presented following the CLP-like forms section of this report.

SDG CASE NARRATIVE

Sample Receipt and Login -- Work Order: 1405452

TriMatrix Laboratories received the cooler(s) for this work order on May 29, 2014, at 10:55am. Receiving documents include field chain-of-custody (COC) record(s), sample receipt form(s), and Client Drop-Off shipping document(s). The condition of the custody seals, the type and location of the coolant, and the temperatures recorded for each cooler are presented on the TriMatrix *Sample Receiving / Log-In Checklist* provided in section A of this package. The receipt temperature of the samples was determined by using an infrared thermometer to record the temperature of three random samples of varying container types and the accompanying temperature blank, if present.

Samples were scheduled for the analyses listed on the corresponding COC form. Field IDs and assigned laboratory identifiers are presented in the table below.

Field Sample Name	Laboratory Sample ID	Matrix	Date Sampled
001	1405452-01	Water	5/28/2014
004	1405452-02	Water	5/28/2014

SDG CASE NARRATIVE

Attachment 1
Project Technical Narrative(s)

Sample Result Reporting Convention

Sample results are reported as RL "U" (e.g. 0.001 U) if the target analyte was not detected above the MDL.

If a sample for an organic analyte is reanalyzed and also reported, the second analysis includes the suffix "RE*n*" where *n* = the first, second, etc. reanalysis.

Percent Solids and Metals Data Reporting

Unless otherwise noted, all soil samples requiring metals analysis are dried at 50° to 60° C to a constant weight prior to acid digestion. In order to report results on a dry weight basis, correction for percent solids is not applicable.

Data Qualifier Designation

If applicable, sample results are qualified with:

a "J" flag if the analyte was detected, but the concentration is greater than the MDL and less than the RL;

a "B" flag if the analyte was also detected at or above the RL in the associated method blank, and the sample concentration was less than five times the method blank result;

a "E" flag if the analyte exceeded the instrument calibration range;

an asterisk (*) if a report-generated statement of qualification applies; qualifying statements, if any, will be found in Attachment 2 to this narrative.

QC Batch and Analytical Batch Designation

A Quality Control (QC) Batch is a seven-digit number that associates all samples that have been prepared together (or analyzed together if there is no preparation). Quality Control batches are limited to no more than twenty samples, excluding batch QC (method blanks, control spikes, etc.). Some batches may contain multiple sets of method blanks (BLK) and laboratory control samples (BS), where a set of method quality control analyses were prepared in concert with each set of samples on a given day.

An Analytical Batch (or Sequence) is a seven-digit number that associates all samples analyzed as a set under one analytical run.

Aqueous Samples: For each sample and container type, check the box if pH is acceptable. If pH is not acceptable for any sample container, record pH in box, and note on Sample Receiving Checklist and on Sample Receiving Non-Conformance Form. If approved by Project Chemist, add acid or base to the sample to achieve the correct pH. Add up to, but do not exceed 2x the volume initially added at container prep (see table below for initial volumes used). Add orange pH tag to sample container and record information requested. Record adjusted pH on this form. Do not adjust pH for container types 3, 6, and 15.

Rerun Macro

TRIMATRIX LABORATORIES

TOTAL SUSPENDED SOLIDS

BATCH OVERVIEW	
Sequence:	4103012
Balance Number:	210
Analysis Date:	06/03/14
Analyst:	WAH
Parameter:	Residue, Suspended
Matrix:	Water
Method Reference:	Solids, TSS 2540 D
Units:	mg/L
Minimum MRL:	2.5

ANALYSIS STEPS

Step	Start Date	Start Time	Start Temp (°C)	End Date	End Time	End Temp (°C)
Step #1	06/03/14	2:00 PM	104.0	06/04/14	8:15 AM	104.0
Step #2	06/04/14	9:30 AM	104.0	06/04/14	10:30 AM	104.0
Step #3						

Step #1: To dryness @ 103-105° C (overnight, to dryness) **in Oven #54 or #56**

Step #2: Second drying @ 103-105° C (1hr) **in Oven #54 or #56**

Step #3: Recheck of Step #2 after further cooling in desiccator (if necessary)

Oven # Used: 54

QUALITY CONTROL

Difference Between Weighings: Less than 0.0005 g

Blank Concentration: Less than 3.3mg/L (at 750 mL)

MS/MSD Precision: <20%

LCS Accuracy: See benchsheet

QC BATCH AND APPROVAL

Batch Number: 1405291

Filter Paper Lot: 600007-4094-R1

Supervisor Approval:
