# Supplemental Field Sampling Plan for Post Cover Placement - Kinnickinnic River Sediment Remediation Project

PREPARED FOR: KK River Project Team

PREPARED BY: CH2M Hill

DATE: November 30, 2009

## Introduction

This *Supplemental Field Sampling Plan* (SFSP) was prepared to provide details on the collection of additional sediment samples to document the post-remedial action (RA) conditions for the Kinnickinnic River (KK River) Sediment Remediation Project (project), within the Milwaukee River Estuary Area of Concern (AOC). The SFSP defines the procedures that will be used to collect these additional data.

CH2M HILL previously prepared a *Field Sampling Plan* (FSP) and *Quality Assurance Project Plan* (QAPP) (dated September 2009) describing the RA investigation that included the collection and analysis of sediment samples. The objectives of initial RA sediment investigation were to characterize sediment thickness and sediment PCB and PAH concentrations following dredging to determine if any additional remedial action was required.

This SFSP was prepared to provide details on the collection of additional sediment samples and discusses those elements that are not included in the original FSP. This plan references the original FSP and QAPP, where appropriate, and does not repeat information presented therein.

## Sampling Objective and Approach

The purpose of the sampling is to characterize sediment PCB and PAH concentrations following cover application. Analytical results will be used to calculate a post remedial action surface weighted average concentration (SWAC) for PCB and PAH concentrations.

Collection of additional samples to calculate the post remedial action SWAC may be necessary and is dependant upon examination and review of the validated post dredge sediment sample data once available.

## Field Operations and Procedures

### Sediment Sampling

Sediment grab samples for the analysis of PCBs and PAHs will be collected at 39 total sample locations as shown in Figure 1.

A two-person crew in a small vessel (john boat) will collect samples using a petite ponar or manually operated sediment core sampler outfitted to collect sediment samples approximately 0.5 feet deep into the post remedial sediment surface to represent surface conditions. If an initial sampling attempt does not provide adequate sample volume due to low recovery, additional attempts will be made at the same location until sample volume requirements are met. If more than one attempt is needed, the total volume of sediment collected for the specific location will be homogenized prior to containerizing using procedures described in the original FSP.

An onboard sub-meter global positioning system (GPS) unit will be used to navigate within 10 feet of the proposed sampling location (Figure 1) and to record the station positioning (x and y coordinates). Field notes at each location will record date, time, personnel, weather conditions, station ID, x,y-coordinates, sediment description, and photographic documentation.

Non-disposable field equipment and sampling devices will be cleaned and decontaminated according to procedures described within SOP-02 of the original FSP. Disposable sampling equipment and PPE will be decontaminated following sampling. Solid and liquid IDW generated during the field work will be containerized and properly disposed of following the completion of field activities in accordance to the original FSP.

Procedures implemented to ensure representative environmental samples are obtained will follow the original FSP and QAPP and include procedures to ensure samples are properly containerized, preserved, shipped, and otherwise handled in a manner that will maintain sample integrity.

## Sample Identification

Each sample will be assigned a CH2M HILL site-specific identifier that will contain a project identification code (KK signifies the Kinnickinnic River remediation project site) and a sample-specific station location identifier with a sequential numbering system, which indicates where the sample was collected.

The site-specific identifier will be based on the following system:

- Site – The site name abbreviation will always be KK.
- Station location – The station location identifier will be the unique name of the sampling location consisting of two letters indicating the type of sample location (“PG” – Ponar Grab), followed by two numerals sequentially generated based on the order in which the sampling was performed. For example, the third ponar grab sample location would be KK-PG03.
- QA/QC identifier – Field QA/QC samples will be identified using the following QA/QC identifiers:
  - Field split samples, which are associated with the same station location as the sample, will be identified with an “S” (for “split”) appended to the end of the location code. For example, the field split sample of sample KK-PG02 would be labeled KK-PG02R.

- Field equipment blanks, which are not associated with an individual station location, will be numbered sequentially and identified by the first two letters of the station location code (for example, EB01 would be for equipment blank).
- Laboratory QA/QC samples – A sample collected for laboratory QC (laboratory spike samples) is considered to be a single sample, even though additional volume is provided to the laboratory. Consequently, all laboratory QC samples will be assigned a single sample number and station location identifier. Laboratory QC samples will not be identified in the station location code, but rather will be called out on the chain-of-custody form in the “Samples to be used for laboratory QC” field and on the sample tag.

Table 1 below describes the sample containers, preservation method, and holding times.

**TABLE 1**  
Sample Containers, Preservation, and Holding Times

Analyte	Container and Minimum Quantity		Preservation	Holding Time
	Water	Soil/Sediment		
PCBs	1 liter/G-A	8 oz/G-TLC	4°C	Soil – 14 days to extraction/40 days to analysis
PAHs	1 liter/G-A	8 oz/G-TLC	4°C	Water – 7 days to extraction/40 days to analysis

Notes:

G-A = glass amber, G-TLC = glass with Teflon-lined cap

## Quality Control Sample Procedures

### Field Splits

Field split samples will be used to measure the heterogeneity of the sample matrix, as well as the level of uncertainty associated with the field sampling and analytical processes. A field split sample will be collected by collecting a subsample from the sample following homogenization and submitting them to the laboratory for individual analysis. Field split samples will be collected at a 10 percent frequency of the samples resulting in four field split samples.

### Equipment Blanks

Equipment blanks will be collected and analyzed to determine whether the decontamination procedure has been adequately performed and that there is no cross-contamination of samples occurring due to the equipment or residual decontamination solutions. At least one equipment blank will be collected for each sampling device utilized during field activities which comes in contact with the sediment samples.

### **Matrix Spike/Matrix Spike Duplicates**

MS/MSD samples will be used by the laboratories to assess the precision and accuracy of sample analysis. The MS/MSD samples will be fortified by the laboratories in accordance with the specifications of the analytical methods. Two extra volumes of sample are required for each combination of MS/MSD samples. Sample containers will be filled and stored in the same manner as field split samples. The frequency for collection of MS/MSD samples will be at least 5 percent, resulting in two MS/MSD samples.

## **Determination of Sample Quantity and Placement**

### **Sample Quantity**

Sample quantity was determined using the “hot spot” design module within Visual Sampling Plan (VSP) version 5 software. The number of proposed sample locations required was determined using a 95 percent probability of locating PCB and PAH results above their respective remedial action levels within a 50 foot radius of the proposed sample location. This approach resulted in 39 sample locations (Figure 2). The search radius of 50 feet was selected based on variograms produced by CSC from pre-remedial data that demonstrated the greatest distance between various depth intervals of PCB and PAH concentrations was 100 feet, which was used in the original post dredge sample design placement (Appendix B, original FSP, September 2009).

However, final sample locations will be based on the practicality of sampling each location (i.e. moving a proposed sample location to avoid, piers, sheet piling, vessels, etc). If an obstruction is encountered the proposed sample location will be adjusted in 10 foot increments parallel with the shoreline until the obstruction is avoided.

### **Proposed Sample Placement**

Proposed sample locations were obtained using VSP software using a triangular grid derived from the 50 foot “hot spot” radius, with a random grid starting point at a randomly selected grid angle. A single zone consisting of the entire project area was utilized for proposed sample placement except in areas receiving rip-rap located under the First Street and Kinnickinnic Avenue bridges (Figure 1). After initial placement of the proposed samples using VSP, a review was conducted to insure that adequate coverage of three sub-zones (center channel and each side slope bank) were appropriately represented by approximately one-third of the proposed samples. This was done to ensure that an adequate quantity of proposed samples would represent the physical subsurface conditions due to sand placement on side sloped areas.
