

Health Effects of Particulate Matter Air Pollution

C. Arden Pope III

Mary Lou Fulton Professor of Economics

Presented at

EPA Wood Smoke Health Effects Webinar

July 28, 2011

What we breath impacts our health

- Pure Air--nitrogen (78%),Oxygen (21%), Argon, CO₂. . .

+

- Various gaseous pollutants including:
 - SO₂, NO₂, CO, O₃ . . .

+

- **Particulate matter:**
 - Course particles (> 2.5 μm in diameter)
 - **Fine particles (< 2.5 μm in diameter)**

+

- Other air toxics

Wood
Smoke

How small are fine particles?

Human Hair
(60 μm diameter)

PM₁₀
(10 μm)

PM_{2.5}
(2.5 μm)

Magnified ambient particles (www.nasa.gov/vision/earth/environment)

Early **“Killer smog”** episodes demonstrated that air pollution at extreme levels can contribute to respiratory and cardiovascular disease and death

Dec. 1-5, 1930: Meuse Valley, *Belgium*
60 deaths (10x expected)

Oct. 27-31, 1948: Donora, PA
20 deaths, ½ the town’s population fell ill

Dec. 5-9, 1952: London--1000’s of excess deaths

Respiratory and cardiovascular
disease and death

London Fog Episode, Dec. 1952

THE BIG SMOKE

From: Brimblecombe P. The Big Smoke, Methu

Utah Valley, 1980s

- Winter **inversions** trap local pollution
- Natural test chamber

- Local Steel mill contributed ~50% $PM_{2.5}$
- Shut down July 1986-August 1987
- Natural Experiment

Large difference in air quality when inversions trap air pollution in valley

Utah Valley: Clean day

Utah Valley: Dirty day
($PM_{10} = 220 \mu\text{g}/\text{m}^3$)

When the steel mill was open, total children's hospital admissions for respiratory conditions **approx. doubled.**

Sources: Pope. Am J Pub Health.1989; Pope. Arch Environ Health. 1991

Intervention/natural experiment (months-years)

Controlled experimental human and animal

Health studies take advantage of **highly variable** air pollution levels that result from inversions.

PM_{2.5} concentrations January 1 1998-December 12 2009. Black dots, 24-hr PM_{2.5}; Red line, 30-day moving average PM_{2.5}; Green line, 1-yr moving average PM_{2.5}.

Daily changes in air pollution \longrightarrow daily death counts

Poisson Regression

Count data (non-negative integer values). Counts of independent and random occurrences classically modeled as being generated by a Poisson process with a Poisson distribution:

$$\text{Prob}(Y = r) = e^{(-\lambda)} \frac{\lambda^r}{r!}$$

Note: λ = mean and variance. If λ is constant across time, we have a stationary Poisson process. If λ changes over time due to changes in pollution (P), time trends, temperature, etc., this non-stationary Poisson process can model as:

$$\ln \lambda_t = \alpha + \beta(w_0 P_t + w_1 P_{t-1} + w_2 P_{t-2} + \dots) + s^1(t) + s^2(\text{temp}_t) + \dots$$

Modeling controversies

How to construct the lag structure? (MA, PDL, etc.)

How aggressive do you fit time? (harmonics vs GAMs, df, span, loess, cubic spline, etc.)

How to control for weather? (smooths of temp & RH, synoptic weather, etc.)

Also: How to combine or integrate information from multiple cities

Daily time-series studies ***of over 200 cities***

10 $\mu g/m^3$ $PM_{2.5}$ or 20 $\mu g/m^3$ PM_{10} → 0.4% to 1.5% increase in relative risk of mortality—Small but remarkably consistent across meta-analyses and multi-city studies.

Panel studies of asthmatics and non-asthmatics

Fig. 1. Daily PM₁₀ levels, mean peak expiratory flow deviations (Δ PEF), percentage who reported cough, and number of participants for the symptomatic sample.

Summary of early Utah Valley epidemiological studies

Health effects

- **Increased hospital admissions**
- **Increased respiratory symptoms**
- **Reduced lung function**
- **Increased school absences**
- **Increased respiratory and cardiovascular deaths**

Jeffrey Anderson

Ischemic Heart Disease Events Triggered by Short-Term Exposure to Fine Particulate Air Pollution

C. Arden Pope III, PhD; Joseph B. Muhlestein, MD; Heidi T. May, MSPH; Dale G. Renlund, MD; Jeffrey L. Anderson, MD; Benjamin D. Horne, PhD, MPH

Methods:

Case-crossover study of acute ischemic coronary events (heart attacks and unstable angina) in 12,865 well-defined and followed up cardiac patients who lived on Utah's Wasatch Front

...and who underwent coronary angiography

Binary Data, classic time-series

Binary Data, case-crossover

Conditional Logistic Reg.

Each subject serves as his/her own control.

Control for subject-specific effects, day of week, season, time-trends, etc.—by matching

Conditional logistic regression:

$$\ln \left(\frac{\text{Prob}(Y_t = 1)}{1 - \text{Prob}(Y_t = 1)} \right) =$$

$$\alpha_1 + \alpha_2 + \alpha_3 + \dots + \alpha_{12,865} + \beta(w_0P_t + w_1P_{t-1} + w_2P_{t-2} + \dots)$$

Control by matching for:

All cross-subject differences

(in this case, 12,865 subject-level fixed effects),

Season and/or month of year,

Time trends,

Day of week

Modeling controversies: How to select control or referent periods. Time stratified referent selection approach (avoids bias that can occur due to time trends in exposure) (**Holly Janes, Lianne Sheppard, Thomas Lumley** *Statistics in Medicine and Epidemiology* 2005)

Figure 1. Percent increase in risk (and 95% CI) of acute coronary events associated with $10 \mu\text{g}/\text{m}^3$ of $\text{PM}_{2.5}$, or PM_{10} for different lag structures.

Short-term PM exposures contributed to acute coronary events, especially among patients with underlying coronary artery disease.

Figure 2. Percent increase in risk (and 95% CI) of acute coronary events associated with $10 \mu\text{g}/\text{m}^3$ of $\text{PM}_{2.5}$, stratified by various characteristics.

An Association Between Air Pollution and Mortality in Six U.S. Cities

The NEW ENGLAND
JOURNAL of MEDICINE 1993

Dockery DW, Pope CA III, Xu X, Spengler JD,
Ware JH, Fay ME, Ferris BG Jr, Speizer FE.

Methods:

- 14-16 yr prospective follow-up of 8,111 adults living in six U.S. cities.
- Monitoring of TSP PM₁₀, PM_{2.5}, SO₄, H⁺, SO₂, NO₂, O₃ .
- Data analyzed using survival analysis, including Cox Proportional Hazards Models.
- Controlled for individual differences in: age, sex, smoking, BMI, education, occupational exposure.

Cox Proportional Hazards Survival Model

Cohort studies of outdoor air pollution have commonly used the CPH Model to relate survival experience to exposure while simultaneously controlling for other well known mortality risk factors. The model has the form

$$\lambda_i^{(l)}(t) = \lambda_0^{(l)}(t) \exp\left(\beta^T x_i^{(l)}(t)\right)$$

Hazard function or instantaneous probability of death for the i^{th} subject in the l^{th} strata.

Baseline hazard function, common to all subjects within a strata.

Regression equation that modulates the baseline hazard. The vector $X_i^{(l)}$ contains the risk factor information related to the hazard function by the regression vector β which can vary in time.

Adjusted risk ratios (and 95% CIs) for cigarette smoking and PM_{2.5}

Cause of Death	Current Smoker, 25 Pack years	Most vs. Least Polluted City
All	2.00 (1.51-2.65)	1.26 (1.08-1.47)
Lung Cancer	8.00 (2.97-21.6)	1.37 (0.81-2.31)
Cardio- pulmonary	2.30 (1.56-3.41)	1.37 (1.11-1.68)
All other	1.46 (0.89-2.39)	1.01 (0.79-1.30)

Particulate Air Pollution as a Predictor of Mortality in a Prospective Study of U.S. Adults

A Special Report of the Institute's Particle
Epidemiology Reanalysis Project

Lung Cancer, Cardiopulmonary Mortality, and Long-term Exposure to Fine Particulate Air Pollution

C. Arden Pope III, PhD

Richard T. Burnett, PhD

Michael J. Thun, MD

Eugenia E. Calle, PhD

Daniel Krewski, PhD

Kazuhiko Ito, PhD

George D. Thurston, ScD

Context Associations have been found between day-to-day particulate air and increased risk of various adverse health outcomes, including cardiopulmonary mortality. However, studies of health effects of long-term particulate air pollution have been less conclusive.

Objective To assess the relationship between long-term exposure to fine particulate air pollution and all-cause, lung cancer, and cardiopulmonary mortality.

Design, Setting, and Participants Vital status and cause of death data were collected by the American Cancer Society as part of the Cancer Prevention II study, a going prospective mortality study, which enrolled approximately 1.2 million adults.

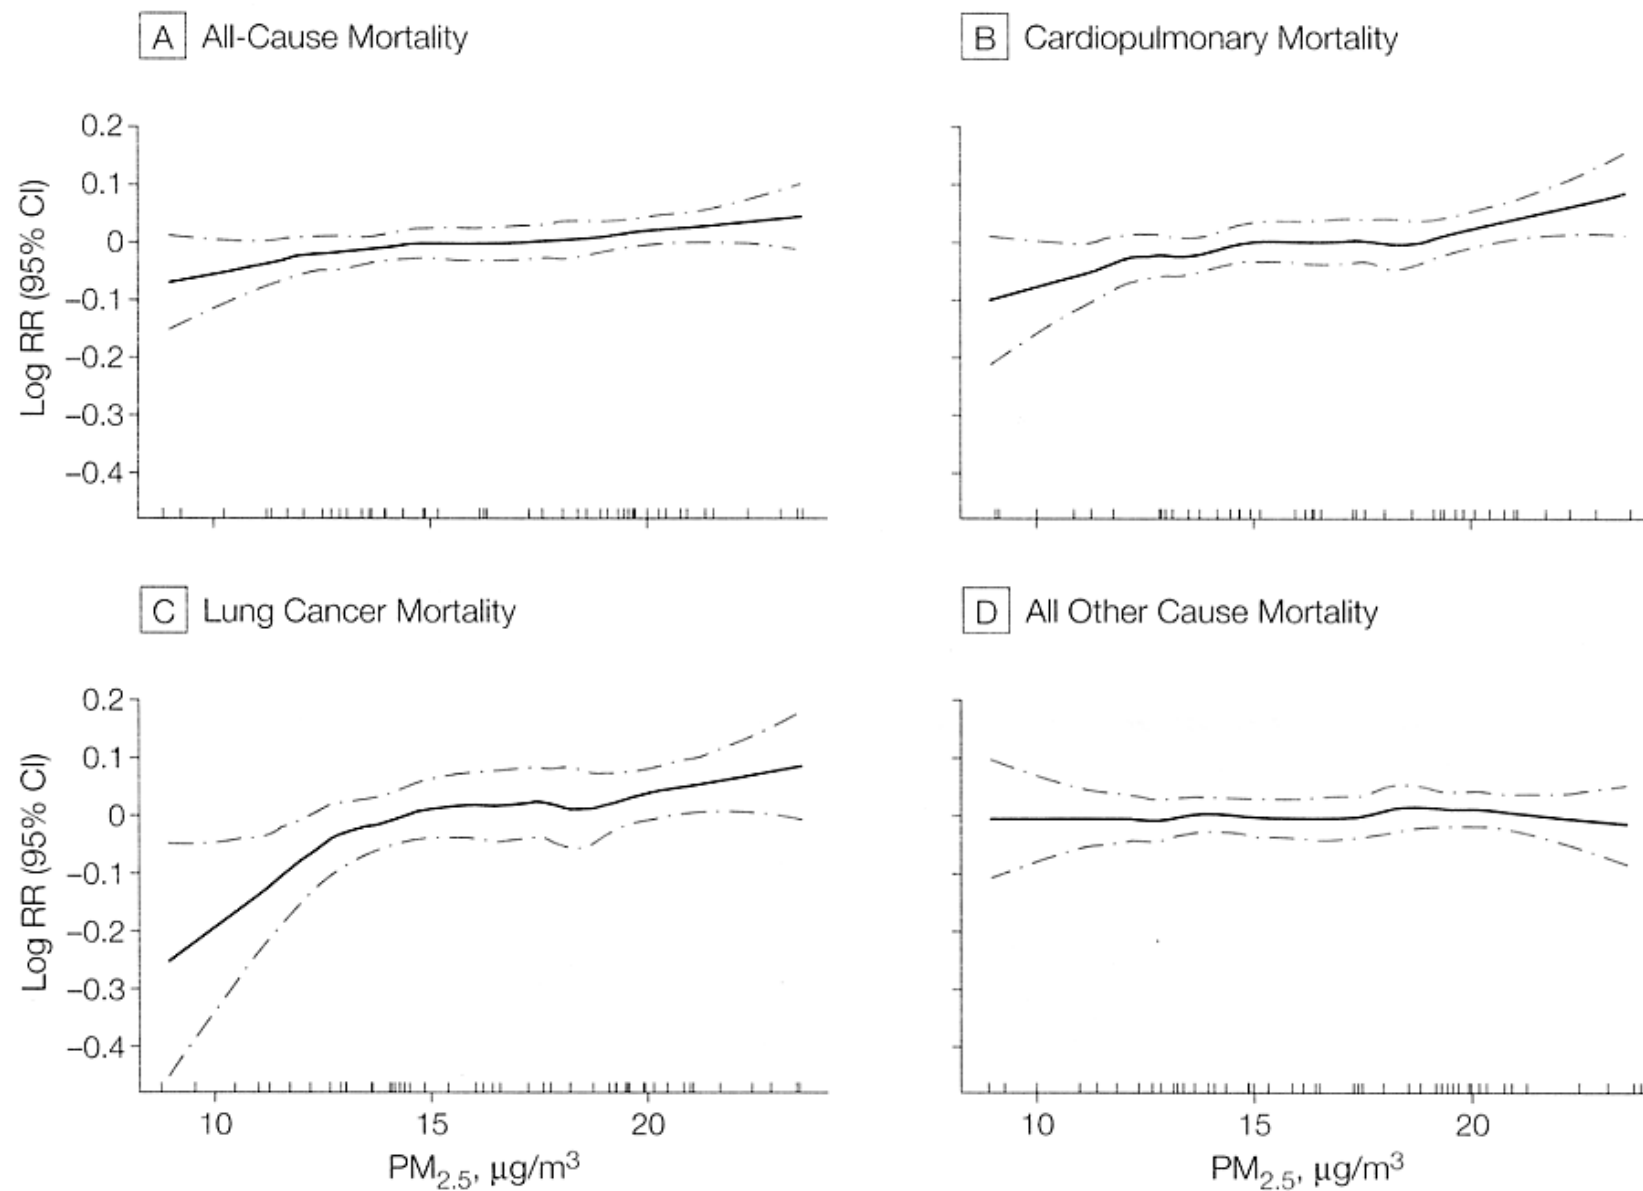

Figure 2. Nonparametric Smoothed Exposure Response Relationship

Cardiovascular Mortality and Long-Term Exposure to Particulate Air Pollution

Epidemiological Evidence of General Pathophysiological Pathways of Disease

Fine-Particulate Air Pollution and Life Expectancy in the United States

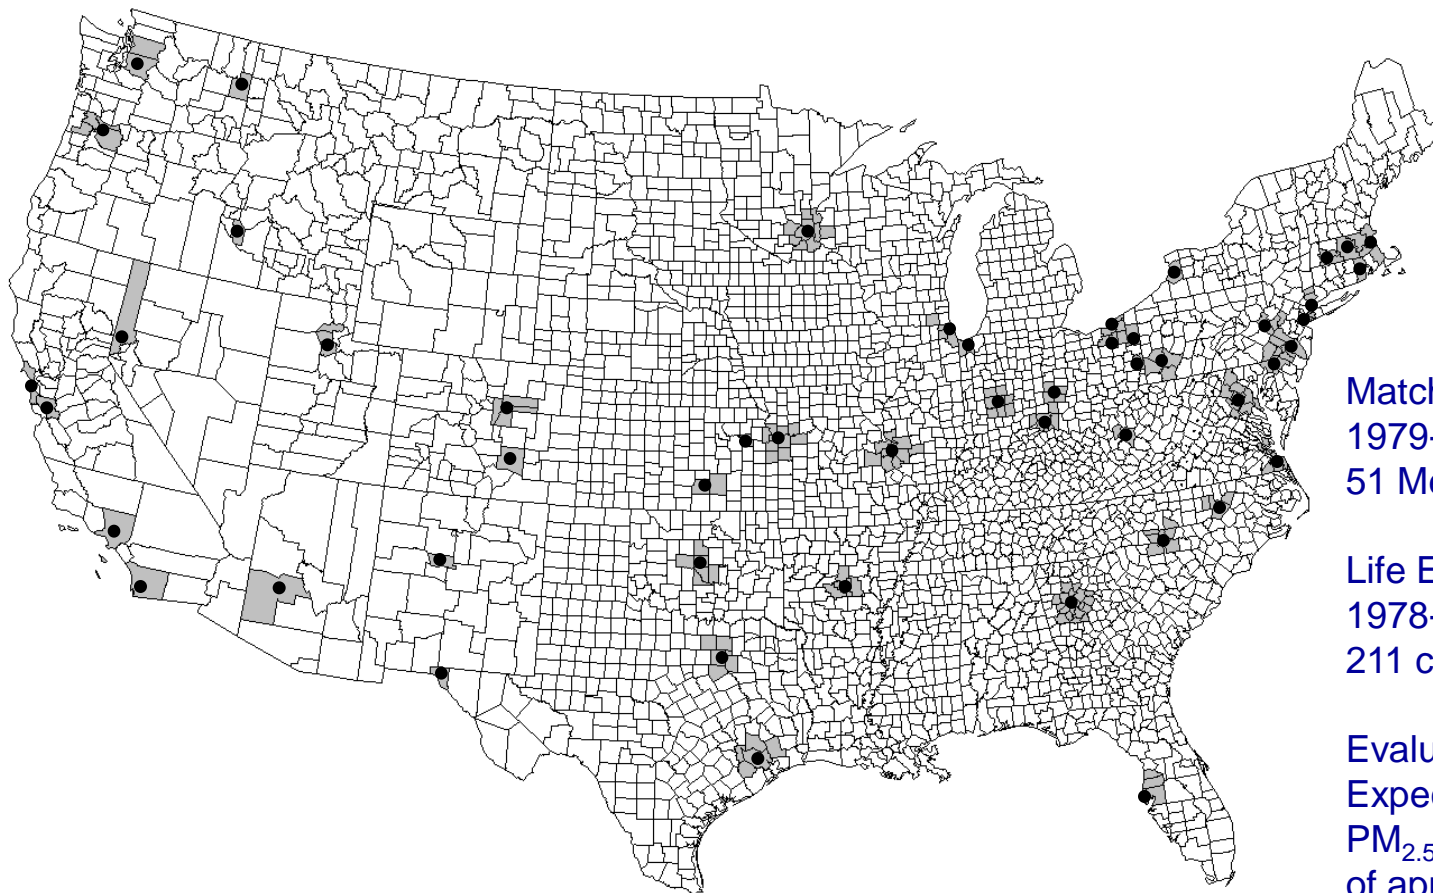

C. Arden Pope, III, Ph.D., Majid Ezzati, Ph.D., and Douglas W. Dockery, Sc.D.

January 22, 2009

Majid Ezzati

Doug Dockery

Matching $PM_{2.5}$ data for
1979-1983 and 1999-2000 in
51 Metro Areas

Life Expectancy data for
1978-1982 and 1997-2001 in
211 counties in 51 Metro areas

Evaluate changes in Life
Expectancy with changes in
 $PM_{2.5}$ for the 2-decade period
of approximately 1980-2000.

Covariates included in the regression models

Changes in socio-economic and demographic variables (from U.S. Census Data):

- Per capita income
- Population
- 5-yr in-migration
- High-school graduates
- Urban population
- Black proportion of population
- Hispanic proportion of population

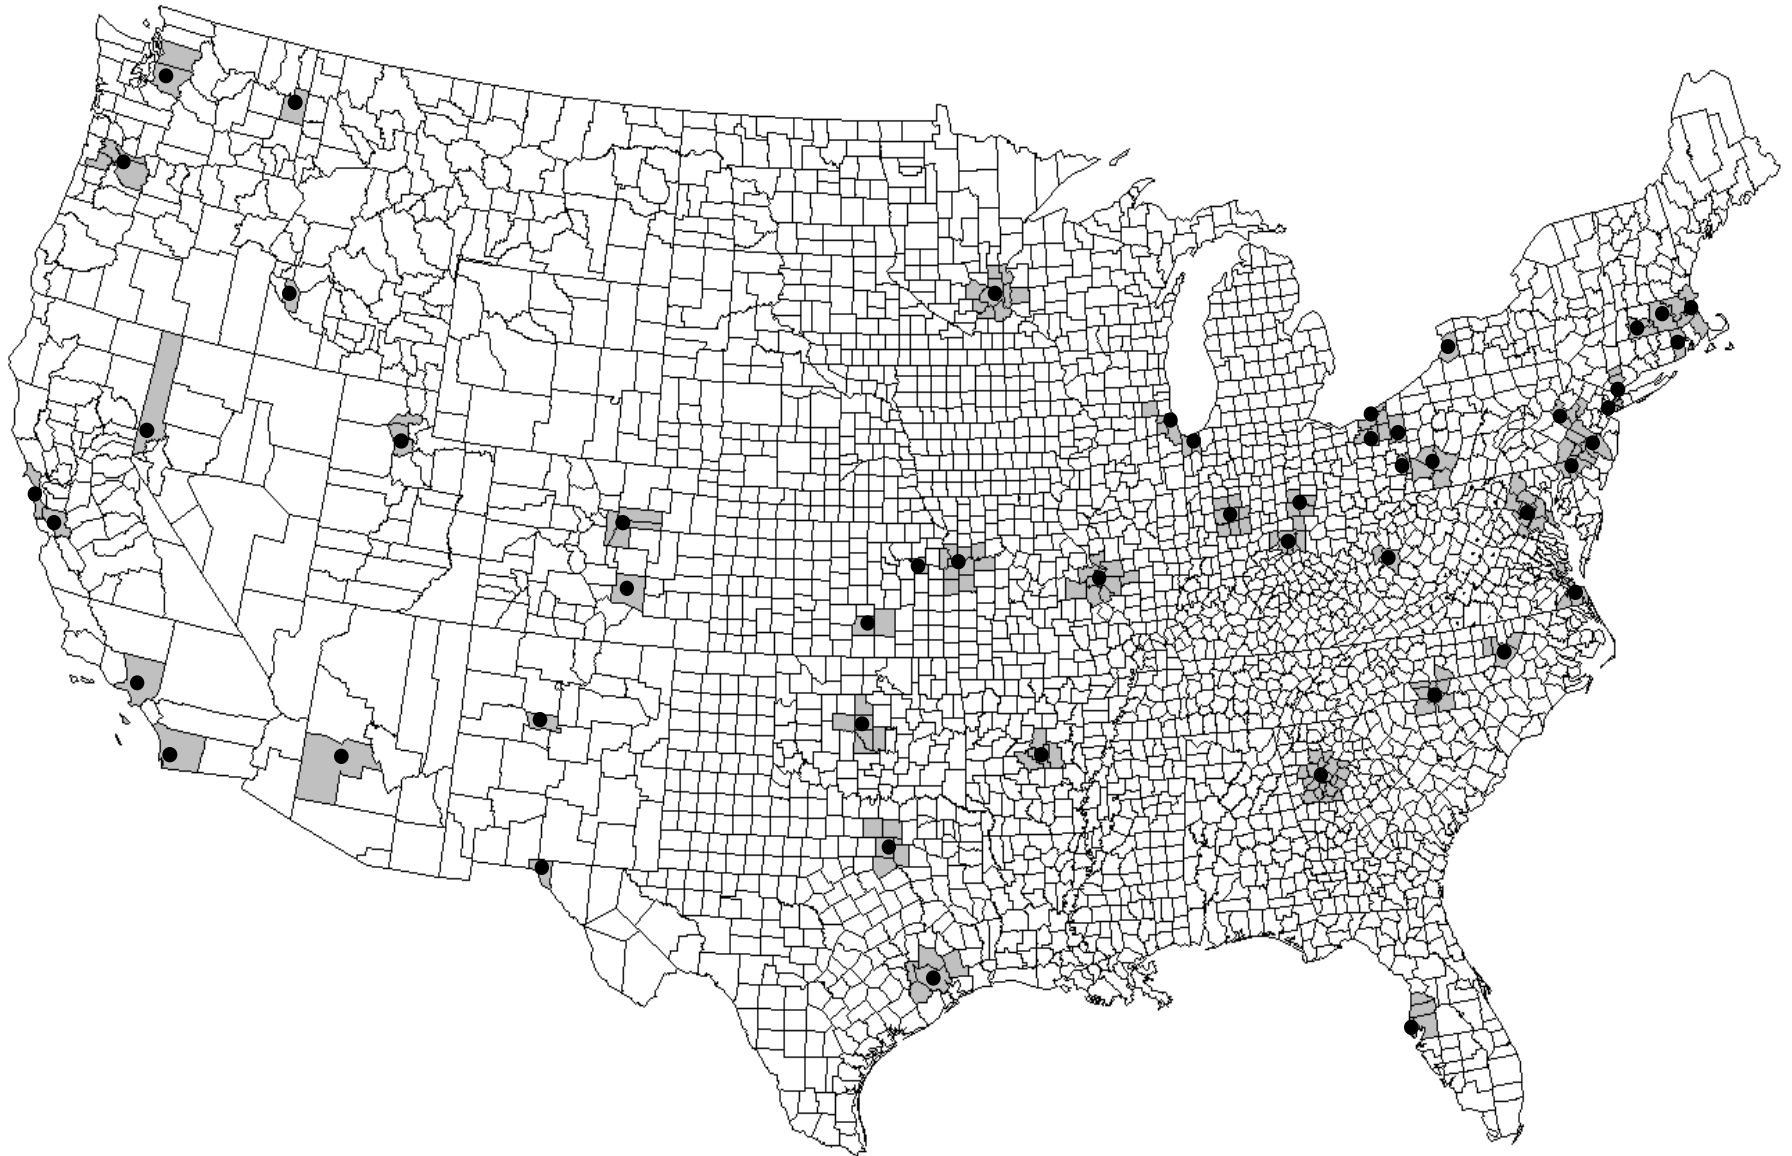

Proxy cigarette smoking variables—available for all 211 counties

- COPD mortality rates
- Lung Cancer mortality rates

Survey-based metro-area estimates of smoking prevalence

- National Health Interview Survey (1978-1980)
- Behavioral Risk Factor Surveillance System (1998-2000)
- Matching data available for only 24 of 51 metro areas

➤ Clustered standard errors (clustered by the 51 metro areas) were estimated for all models except for analysis that included only the 51 largest counties in each metro area.

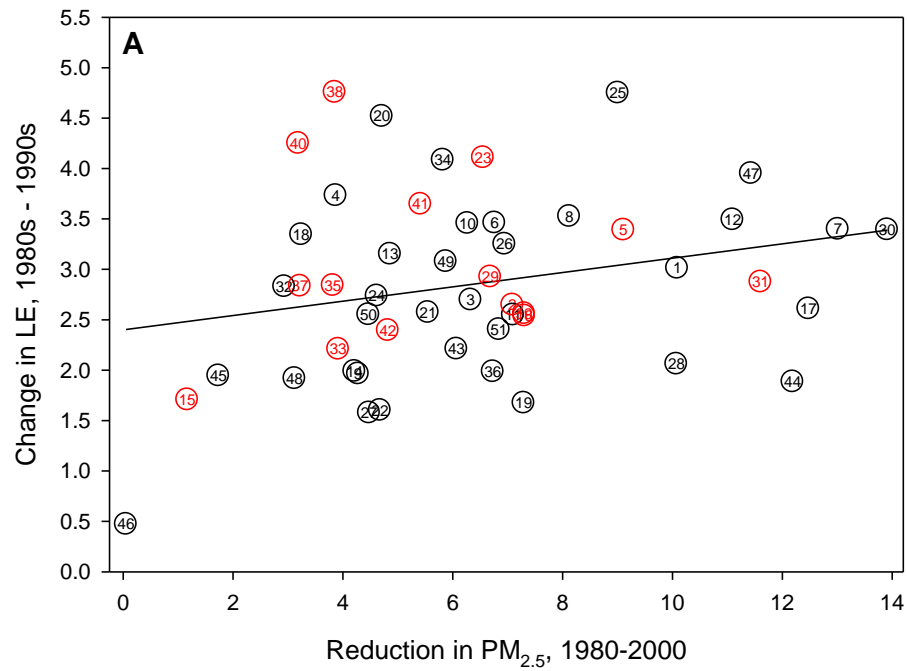

A $10 \mu\text{g}/\text{m}^3$ decrease in $\text{PM}_{2.5}$ was associated with a **7.3 (± 2.4) month** increase in life expectancy.

Table 2. Results of Selected Regression Models, Including Estimates of the Increase in Life Expectancy Associated with a Reduction in $\text{PM}_{2.5}$ of $10 \mu\text{g}$ per Cubic Meter, Adjusted for Socioeconomic, Demographic, and Proxy Indicators for Prevalence of Smoking.*

Variable	Model 1	Model 2	Model 3	Model 4	Model 5†	Model 6‡	Model 7‡

Controlled experimental human and animal

Cardiovascular disease as part of chronic and acute inflammatory processes.

By the early 2000s, there was increasingly compelling evidence that inflammation is a major accomplice with LDL cholesterol in the initiation and progression of atherosclerosis.

Furthermore, inflammation contributes to acute thrombotic complications of atherosclerosis, increasing the risk of making atherosclerotic plaques more vulnerable to rupture, clotting, and precipitating acute cardiovascular or cerebrovascular events (MI or ischemic stroke).

Paul Ridker

Interactive effects of hs-CRP (marker of inflammation) and blood lipids.

Fine Particulate exposure

Pulmonary and systemic inflammation and oxidative stress

(along with blood lipids)

Progression and destabilization of atherosclerotic plaques

Experimental evidence of biological effects of PM extracted from filters
(Ghio, Costa, Devlin, Kennedy, Frampton, Dye, et al. 1998-2004)

- Acute airway injury and inflammation in rats and humans
- *In vitro* oxidative stress and release of proinflammatory mediators by cultured respiratory epithelial cells
- Differential toxicities of PM when the mill was operating versus when it was not (metals content and mixtures?)

A series of studies by van Eeden, Hogg, Suwa et al. (1997-2002) suggest:

In rabbits naturally prone to develop atherosclerosis they found that:
