Air Quality Modeling Session

9/26/23

Background

- Emissions inventories play a crucial role in the study of air quality in areas with pollution.
- There are annual emissions inventories available for specific years (NEIM **2006, 2008, 2014, 2016**) compiled by SEMARNAT and INECC
- They lack certain characteristics required for use in air quality models. Specifically, these inventories lack the necessary features, such as hourly temporal distribution, data organized in a regular grid, and information on the chemical species necessary for the chemical mechanisms used in these models.
- Therefore, there is a need for a system to convert NEIM data into a format suitable for air quality modeling.

In collaboration with JAICA

Ancillary data from SMOKE

Mass balance verification

Mass conservation if $Mo=Ma=Mt=Ms$

In the spatial distribution, there were emissions that were not located due to the lack of agricultural land cover (3%).

Mass balance variation in Speciation

		Mobile	Point	Area
Mg/day	TOC (Mg/day)	1436	181	9056
CB05	Speciation	4398	457	27160
	% Diference	206%	153%	200%
MOZART	Speciation	1214	95	5395
	% Diference	-15%	-47%	-40%
RACM2	Speciation	1214	155	1104
	% Diference	-15%	-15%	-8%
RADM2	Speciation	1156	142	8220
	% Diference	-19%	-22%	-9%
SAPRC99	Speciation	1216	172	8570
	% Diference	-15%	-5%	-5%

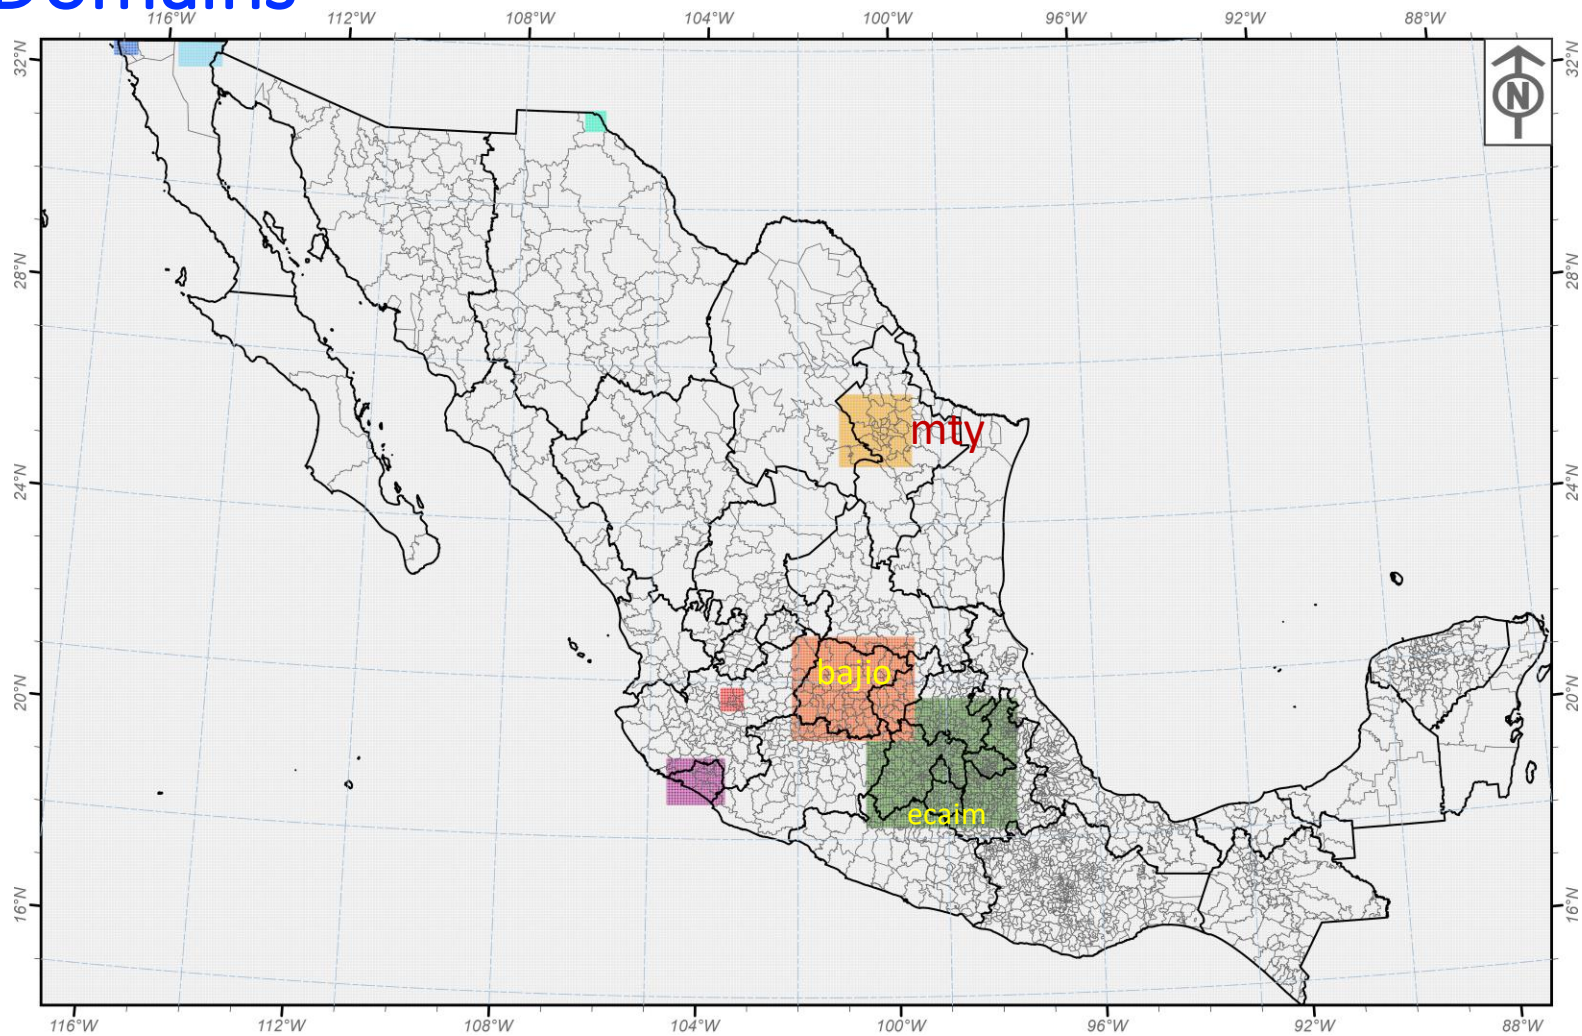

In speciation: Diferences are due to non volatile and non reactive compounds
 TOC > VOC

Results

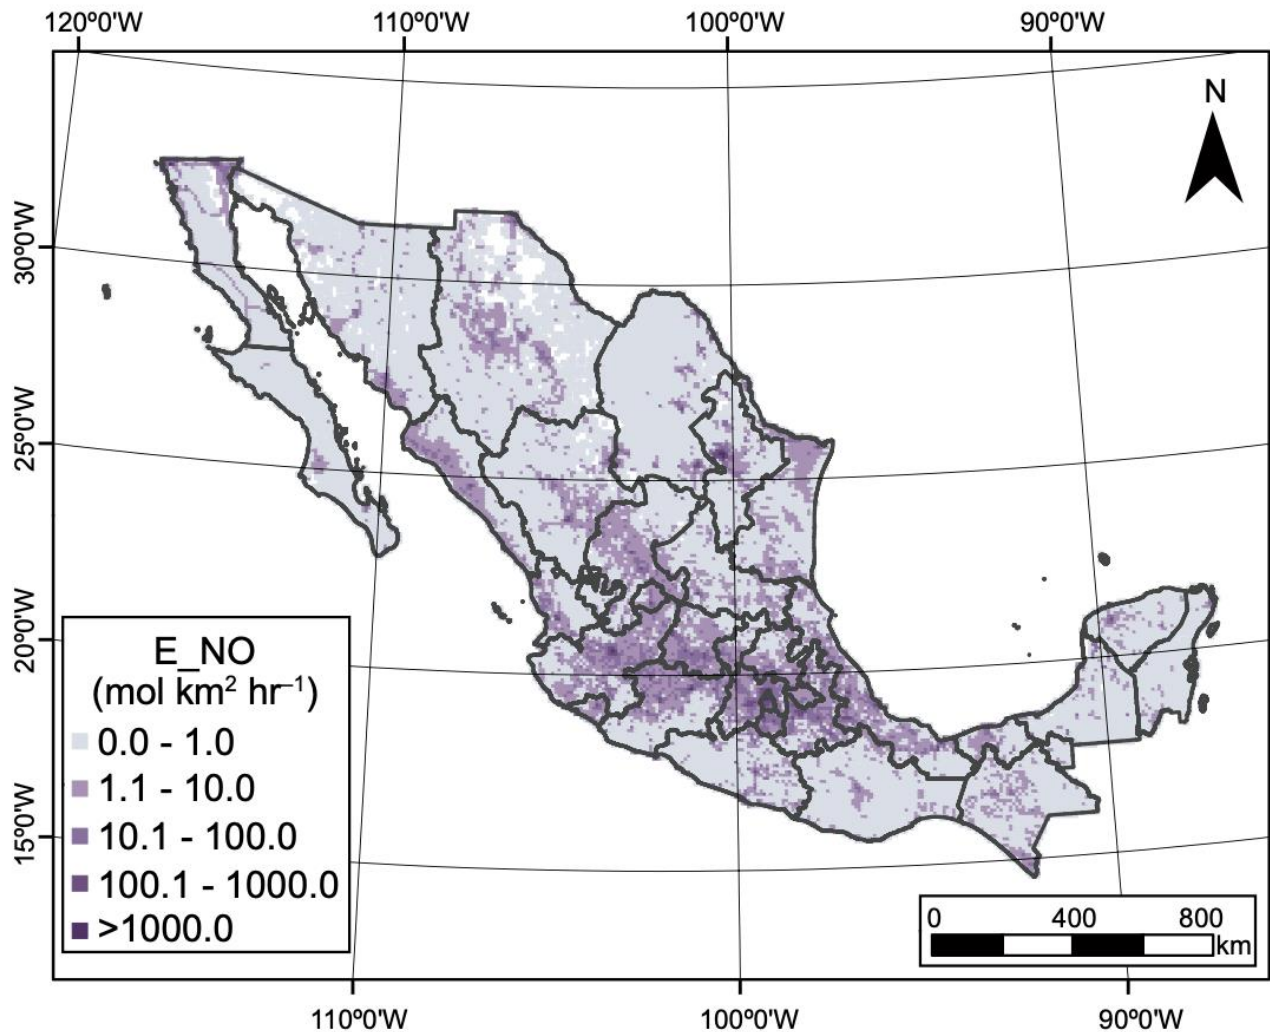

National Emissions Inventory 2016 is converted in order to be used in air quality modeling.

Speciation

Carter WPL (2000) Documentation of the SAPRC-99 chemical mechanism for VOC reactivity assessment vol1.
California Air Resources Board. Research Division, California, EU

Carter WPL (2015) Development of a database for chemical mechanism assignments for volatile organic emissions
Journal of the Air and Waste Management Association 65:1171-1184 doi:10.1080/10962247.2015.1013646

Discussion

- Land cover, streets, highway and population were used for the spatial distribution.
 - Some grids near urban areas has no agricultural land cover therefore emissions were not allocated.
 - Mobile emissions are allocated by highway area surface
- Mexican emission categories were mapped to SCCs
- SCC were used for temporal profiles and chemical speciation.
- Speciation from Carter were used to lump chemical species into chemical mechanism.
- Different number of area emissions categories between 2014 and 2016.

Conclusions

- We have developed a system designed for the conversion of MNEI data
- There are 15 domains from national wide to some specific regions, grid sizes are from 9x9 to 1x1 km
- 6 different chemical mechanism are available and GHG
- NETCDF output files for WRF-chem, CMAQ and CHIMERE
- Code available from: https://github.com/JoseAgustin/emis_2016
- More details in : [DOI: 10.20937/RICA.2018.34.04.07](https://doi.org/10.20937/RICA.2018.34.04.07)

Nexsteps

- Conversion of the 2018 NEIM when available.
- Evaluation of 2018
- Development of emissions from evaporative area and point sources using temperature from the meteorological model.
- Inclusion of traffic activity in highways
- Obtaining local emission factors (i.e. combustion of LPG in homes)
